Vac =3D 339.41 sin[(2*Pi*f)t] where (2*Pi*f) is 376.99 for 60 Hz or = 314.159 for 50 Hz power

Vac =3D 339.41 sin(376.99*t)

=20

Since this is a symmetrical waveform, the _average_ value is 0 while the = _peak_ positive voltage is 339.41 volts.

=20

Now let us apply this voltage to a 1000 ohm resistor. Using Ohm's

Law, we can calculate the current, I=3DV/R.

=20

Iac =3D 339.41 sin(376.99*t) volts/1000 ohms

Iac =3D 0.33941 sin(376.99*t) amps

=20

Again this a symmetrical waveform with an average of 0, and a peak = positive current of 0.33941 amps.

=20

The instantaneous power dissipated by this resistor can be calculated by =
multiplying the voltage by the current.

=20

Pac =3D 339.41 sin(376.99*t) * 0.33941 sin(376.99*t) watts

Pac =3D 115.20 [sin(376.99*t) * sin(376.99*t)] watts

=20

Using a trigonometric identity =
(http://en.wikipedia.org/wiki/List_of_trigonometric_identities) this can =
be rearranged to:

=20

Pac =3D 115.20 * [1 - cos(2*376.99*t)]/2 watts

=20

It is important to understand this function. The value of this function =
goes from zero to a peak of 115.20 watts at twice the frequency of the =
original waveform. The average value is no longer zero but is now 57.6 =
watts. =20

=20

Now let us go back to using RMS values. Since the waveform is =
sinusoidal, we can use some common formulas.

=20

Vrms =3D 0.707107 * Vpeak =3D 0.707107 * 339.41 =3D 240 volts

Irms =3D 240/1000 =3D 0.240 amps

Prms =3D 240 * 0.24 =3D 57.6 watts=20

=20

This is exactly the same as the average of the power calculated above. =
If we had applied 240 volts DC to the 1000 ohm resistor, the power would =
again be 57.6 watts.

=20

Now let us half-wave rectify the original AC waveform. The peak voltage =
will be the same as before, 339.41 volts. But the waveform is no longer =
symmetrical about zero. The average value is:

=20

Vavg =3D Vpeak/Pi =3D 339.41/3.14159 =3D 108.038 volts

=20

The RMS value is:

=20

Vrms =3D Vpeak/2 =3D 169.706 volts

=20

Applying this to the same 1000 ohm resistor gives a current of

=20

Irms =3D Vrms/1000 =3D 0.169706 amps

=20

The RMS power dissipated by the resistor is=20

=20

Prms =3D Vrms * Irms =3D 28.8 watts

=20

Note that this exactly _twice_ the power if the waveform had not been =
rectified.

Now let us do the same calculations for a symmetrical square wave.

=20

Vpeak =3D 339.41 volts

=20

Vavg =3D 0 volts

=20

Vrms =3D 339.41 volts

=20

Ipeak =3D 0.33941 amps

=20

Iavg =3D 0 amps

=20

Irms =3D 0.33941 amps

=20

Prms =3D 115.2 watts

=20

If the square wave is half wave rectified,

=20

Vpeak =3D 339.41 volts

=20

Vavg =3D 169.71 volts

=20

Vrms =3D 169.71 volts

=20

Ipeak =3D 0.33941 amps

=20

Iavg =3D 0.16971 amps

=20

Irms =3D 0.16971 amps

=20

Prms =3D 28.80 watts

=20

Note that this is exactly the same as with the sinusoidal waveform. =
This is exactly the point, half wave rectification produces =
_one_half_of_the_power_ that would be produced by the original =
sinusoidal AC waveform. It does not produce half of the original peak =
voltage. It produces SQRT(2)/2 times the original RMS voltage.

=20

As for your numbers, Ray, you need a refresher course in mathematics. =
As for DVM, VTVM, or VOM readings, you will have to specify the =
filtering of the waveform before I can tell you the value. In the case =
of the CRT filament

(and I really think you might mean the HV rectifier filament) power is =
supplied by a waveform having a high peak value but an RMS value that is =
low. Again you would need to specify the waveform exactly.

=20

There is a very simple way to prove that my calculations are right. Get =
two incandescent light bulbs of the same type and wattage. Wire a diode =
of adequate voltage and current rating in series with one bulb and =
connect to the wall outlet. Use a variac to feed the second bulb. With =
the bulbs side by side, adjust the variac until both bulbs are the same =
brightness. Measure the variac output voltage. You will find that it =
is not 50% of the line voltage but instead very close to 70.7% of the =
line voltage.

=20

In fact, the most accurate RMS voltmeters operate in a similar fashion. =
They let the unknown voltage heat a resistor. Then they use an =
adjustable DC voltage to heat an identical resistor. When both =
resistors are at the same temperature, the DC voltage is the RMS value =
of the unknown voltage. Consult the Linear Technology LT1088

datasheet for a description of one method of doing this. =
http://www.datasheetcatalog.org/datasheet/lineartechnology/lt1088.pdf

=20

The same company also offers several other RMS-to-DC converters that =
operate on a delta-sigma computation technique.

http://www.linear.com/pc/downloadDocument.do?navId=3DH0,C1,C1154,C1086,D4=
486

=20

A general discussion of RMS measurements may be found at:

http://www.edn.com/contents/images/46857.pdf.

=20

This last reference shows typical errors for different types of RMS =
measuring meters. I strongly suggest to anyone still confused to read =
it. And I really hope Phil tries the experiment I suggested.

=20

```
        73, Barry L. Ornitz, PhD   WA4VZQ

  Hey OM
  I beg to differ. As any casual observer can see that peek is 330V and
  the average would be 0.363 of the peak so that's 40 volts in my
  calculator all day long, for a 3 tube string.
```

Lets take a square wave, the average would be 0.5 of peek, far lower
than 0.707 you are used to using. Even if it was full wave 120 cycle
dc, the average would only be 0.636 still lower than 0.707.

I tell you what. Take a diode and rectify the mains with it and
measure the DC voltage with a DVM, VTVM or a VOM and 0.363 of peak is
what you will get for a DC voltage on that meter. Or do the real
integral of the dv/dt and see for yourself.

The TV repair business I was in manufacturers put 50volt peak on a CRT
6.3volt filament, the average voltage was 6.3 volts. Lets see you RMS
that one.

73 OM

n8zu
Ray,

You obviously do not understand the meaning of RMS as you are confusing =
the average voltage with the RMS voltage. In a resistive circuit, the =
RMS voltage of any waveform will produce identical _heating_ as a DC =
voltage of the same value. This is an important point which is often =
overlooked, and it is why measuring the RMS value of a waveform is =
difficult. Let's start with some numbers but avoiding the use of =
integration...

Assume we have an AC voltage described by:

Vac =3D 339.41 sin[(2*Pi*f)t] where (2*Pi*f) is 376.99 for 60 Hz or =
314.159 for 50 Hz power
Vac =3D 339.41 sin(376.99*t)

Since this is a symmetrical waveform, the _average_ value is 0 while the =
peak positive voltage is 339.41 volts.

Now let us apply this voltage to a 1000 ohm resistor. Using Ohm's
Law, we can calculate the current, I=3DV/R.

Iac =3D 339.41 sin(376.99*t) volts/1000 ohms
Iac =3D 0.33941 sin(376.99*t) amps

Again this a symmetrical waveform with an average of 0, and a peak =
positive current of 0.33941 amps.

The instantaneous power dissipated by this resistor can be calculated by =
multiplying the voltage by the current.

Pac =3D 339.41 sin(376.99*t) * 0.33941 sin(376.99*t) watts
Pac =3D 115.20 [sin(376.99*t) * sin(376.99*t)] watts

Using a trigonometric identity =
(http://en.wikipedia.org/wiki/List_of_trigonometric_identities) this can =

be rearranged to:

    Pac =3D 115.20 * [1 - cos(2*376.99*t)]/2 watts

It is important to understand this function. The value of this function = goes from zero to a peak of 115.20 watts at twice the frequency of the = original waveform. The average value is no longer zero but is now 57.6 = watts. =20

Now let us go back to using RMS values. Since the waveform is = sinusoidal, we can use some common formulas.

    Vrms =3D 0.707107 * Vpeak =3D 0.707107 * 339.41 =3D 240 volts
    Irms =3D 240/1000 =3D 0.240 amps
    Prms =3D 240 * 0.24 =3D 57.6 watts=20

This is exactly the same as the average of the power calculated above. = If we had applied 240 volts DC to the 1000 ohm resistor, the power would = again be 57.6 watts.

Now let us half-wave rectify the original AC waveform. The peak voltage = will be the same as before, 339.41 volts. But the waveform is no longer = symmetrical about zero. The average value is:

    Vavg =3D Vpeak/Pi =3D 339.41/3.14159 =3D 108.038 volts

The RMS value is:

    Vrms =3D Vpeak/2 =3D 169.706 volts

Applying this to the same 1000 ohm resistor gives a current of

    Irms =3D Vrms/1000 =3D 0.169706 amps

The RMS power dissipated by the resistor is=20

    Prms =3D Vrms * Irms =3D 28.8 watts

Note that this exactly _twice_ the power if the waveform had not been = rectified.
Now let us do the same calculations for a symmetrical square wave.

    Vpeak =3D 339.41 volts

    Vavg =3D 0 volts

    Vrms =3D 339.41 volts

    Ipeak =3D 0.33941 amps

    Iavg =3D 0 amps

    Irms =3D 0.33941 amps

    Prms =3D 115.2 watts

If the square wave is half wave rectified,

    Vpeak =3D 339.41 volts

    Vavg =3D 169.71 volts

    Vrms =3D 169.71 volts

    Ipeak =3D 0.33941 amps

    Iavg =3D 0.16971 amps

    Irms =3D 0.16971 amps

    Prms =3D 28.80 watts

Note that this is exactly the same as with the sinusoidal waveform. =
This is exactly the point, half wave rectification produces =
_one_half_of_the_power_ that would be produced by the original =
sinusoidal AC waveform. It does not produce half of the original peak =
voltage. It produces SQRT(2)/2 times the original RMS voltage.

As for your numbers, Ray, you need a refresher course in mathematics. =
As for DVM, VTVM, or VOM readings, you will have to specify the =
filtering of the waveform before I can tell you the value. In the case =
of the CRT filament
(and I really think you might mean the HV rectifier filament) power is =
supplied by a waveform having a high peak value but an RMS value that is =
low. Again you would need to specify the waveform exactly.

There is a very simple way to prove that my calculations are right. Get =
two incandescent light bulbs of the same type and wattage. Wire a diode =
of adequate voltage and current rating in series with one bulb and =
connect to the wall outlet. Use a variac to feed the second bulb. With =
the bulbs side by side, adjust the variac until both bulbs are the same =
brightness. Measure the variac output voltage. You will find that it =
is not 50% of the line voltage but instead very close to 70.7% of the =
line voltage.

In fact, the most accurate RMS voltmeters operate in a similar fashion. =
They let the unknown voltage heat a resistor. Then they use an =
adjustable DC voltage to heat an identical resistor. When both =
resistors are at the same temperature, the DC voltage is the RMS value =
of the unknown voltage. Consult the Linear Technology LT1088
datasheet for a description of one method of doing this. =
http://www.datasheetcatalog.org/datasheet/lineartechnology/lt1088.pdf

The same company also offers several other RMS-to-DC converters that =
operate on a delta-sigma computation technique.
http://www.linear.com/pc/downloadDocument.do?navId=3DH0,C1,C1154,C1086,D4=

A general discussion of RMS measurements may be found at:
http://www.edn.com/contents/images/46857.pdf.

This last reference shows typical errors for different types of RMS =
measuring meters. I strongly suggest to anyone still confused to read =
it. And I really hope Phil tries the experiment I suggested.

```

I dont have a problem with crimp on terminals just that where I work
someone has always borrowed the crimp tool just when I need it. I
always have my trusty soldeing gun handy, no one wants to borrow it.
For me one is as easy and works as well as the other. The biggest
problem I have with the non crimp type is the shield is eventually
cut from the connector. The ones at work that are disconnected weekly
for preventive maintenance have only lasted about 20 years before
needing the connectors replaced, BUMMER. The crimp-on type are not
without their problems. I was doing an inspection after some equipment
installation and was able to pull the the ends off of 20 BNC
connectors. The inspection stopped at that point and the decision was
made to reaccomplish all of the connectors, about 200 of them. The
installer was not happy. The problem turned out to be a bad crimp
tool. Like the solder-ons if done properly they are both reliable
connections.

Jimmie

I know the problem. Tools are expensive. However, there are a
variety of cheap replacements that seem to work well for me:
<http://802.11junk.com/jeffl/antennas/Misc/slides/crimpers.html>
I have several sets of these that cover everything from RG-188 to
LMR-400 size coax. There's also one for LMR-600 but it was being
borrowed when I took the photo. (Yes, it came back eventually). I
think I paid about $35/ea for the tools in the photo. At that price,
spares are an option.

>I
>always have my trusty soldeing gun handy, no one wants to borrow it.

When I was working on the bench, I had my soldering iron bolted to a
large block of wood to discourage the borrowers. My biggest problem

was someone trading or outright stealing my Weller solder tips. I kept my supply locked up and hidden.

>For me one is as easy and works as well as the other.

I beg to differ. Many of my connector installs had to be done in the field, usually at a mountain top repeater site or up on a tower. The problem was that the wind would cool just about any soldering iron, gun, or even a propane torch, sufficiently to cause problems. Same with the USCG vessels, where the coax was snaked through the mast, and the connector had to be crimped at the top in the field. The only place where I would effectively solder a connector was inside a building. I do recall one day on a tower, when I draped my jacket over my head, and soldered some connector by flashlight, but I don't recommend doing that.

>The biggest
>problem I have with the non crimp type is the shield is eventually
>cut from the connector.

Agreed. I have the problem with my test cables. A good strain relief is a big help at immobilizing the shield. Pomona jumper cables have molded plastic strain relief's. I use clear shrink tube (so I can see when things are starting to come apart). In general, it's nut much of a problem as I have far more UG-88/u BNC plugs fall apart than the crimped variety.

>The ones at work that are disconnected weekly
>for preventive maintenance have only lasted about 20 years before
>needing the connectors replaced, BUMMER.

Weekly? 52 weeks per year times 20 years is over 1000 connector cycles. That's quite a few. I suspect the ears on the BNC jacks will also be worn. I'm not surprised that they're failing. I did some Googling and found specs for UG-88/u connectors ranging from 500-1000 mating cycles. Methinks you're at the upper limit of the lifetime.

>The crimp-on type are not
>without their problems. I was doing an inspection after some equipment
>installation and was able to pull the the ends off of 20 BNC
>connectors. The inspection stopped at that point and the decision was
>made to reaccomplish all of the connectors, about 200 of them. The
>installer was not happy. The problem turned out to be a bad crimp
>tool. Like the solder-ons if done properly they are both reliable
>connections.

Bummer. At one employer, we had an Amp-o-lectric crimping machine. Someone found that it was possible to mis-adjust the tool to produce defective crimps and proceeded to explore the possibilities. I was blessed with dozens of field failures and a recall because nobody had thought to run a pull test on the crimped connections. Everyone assumed the machine could do no wrong. However, that's the big advantage of a crimped connection... it's consistent. I can't get that kind of consistency from soldered connectors, especially those done in the field.

Incidentally, I've seen more damage done by the razor blade coax stripping tools, than by the crimping or soldering. One nick in a solid center conductor and the center pin connection falls apart inside the connector. I try to use a thermal wire stripper, but that also takes some skill.

>Jeff Liebermann wrote:
>>
>> Good point, but that's not what I had in mind. I was aware of the problem and suggested that the power control be run by a micro. The algorithm needs to be worked out, but basically, the weakest signal sets the power level. The range of power adjustment also will not be huge or large enough to have much of an effect on distant stations. Our current 60 watt amplifier might have the power output reduced to about 20 watts or 4.5dB power reduction. That's less than one S-unit and probably wouldn't be noticeable even by distant stations. However, it will make a huge difference in power consumption and battery operation run time.

>Would it? A lot of amplifiers don't change their power consumption all that much, especially if they're designed for saturated operation (i.e. if you reduce the input drive, they either distort, or drop into linear mode and dissipation goes up).

For FM repeater use, the amplifiers are usually Class C or overdriven Class AB. The output devices are alternately driven into saturation and cutoff. I have some measurements somewhere for our various repeaters buried somewhere. As I vaguely recall, the overall system efficiency was about 50% for VHF and about 35% for the UHF repeater. Of course, everything is properly logged and documented:
<http://www.LearnByDestroying.com/k6bj/K6BJ%20Repeater/slides/Documentation.html>

There are a variety of methods of reducing power, but for Class C, the easiest is to reduce the collector or drain voltage on the RF output stages. This works well down to about 20% of rated output power, but often causes nasty oscillations and parasitics. It also burns quite a bit of power in the linear voltage regulator. Not ideal, but I know it works from experience designing marine VHF radios, which were adjustable and stable from 10-25 watts RF out.

My guess(tm) is that the VHF rack burns about 10A in transmit at 13.6VDC. The UHF box burns about 15A in transmit. The idea is to reduce this to the absolute minimum, and still have a usable machine. Ideally, the power control should be automatic.

You're correct that the efficiency drops badly at lower power, but reducing the overall current consumption is the goal here. The efficiency may be lousy at low power, but if the overall current consumption drops proportionately, it's good enough. The idea is to be able to run the repeater for several days, in an emergency, on battery power:
<http://www.LearnByDestroying.com/k6bj/K6BJ%20Repeater/slides/Batteries.html>
I might setup a switching regulator to reduce the power dissipated in the voltage regulator circuit. I've never tried this but it seems easy enough. Power amp distortion is not an issue here as the FM repeater doesn't have any linear components in the RF signal.

The K6BJ repeater:
<http://www.k6bj.org>
<http://www.LearnByDestroying.com/k6bj/K6BJ%20Repeater/index.html
<http://www.LearnByDestroying.com/k6bj/IRLP/index.html>

>if you have an amplifier designed for variable power output, then what
>you say might be a good idea.

Nope. None of the amps are designed to be operated that way. Few commerical FM transmitters and power amps are designed for adjustable power. Such details have never stopped me in the past. However, club politics, other priorities, and my health issues have slowed me down, thus nothing has been done.

are you just trying to learn the terminology or do you really
need to make some connectors and seek the best/easiest? way to
do that??

if you did you got a bunch of good tips here from the others

>
> Thanks.

i'll throw in a few other simular options to connectors

there are strip tools that can cleanly and safely strip the coax
they just spin around and do a great job i've seen cost between 50
to 100bucks depending on coax

also you can get a fixed center pin whereby you don't have to
solder or crimp, the captivated connectors the outer
sheild part gets a crimp only typically a bit of glue on the
inside heavy ga heat shrink shrink goes over all

they are rated very good soare are the center pins /outer shield
that gets crimped using the right tool of course

no matter what you use skills at doing the job and
inspection/testing of the work will always remain a constant

Dittos, can short internally too.

If it is anything important, the cable should be swept or at least checked for return loss at a higher frequency. Just in case the parts were mismatched out of the bag. Quality control can be a batch problem even in the high end stuff. Good help is hard to find.

I learned to make cables while assisting installation of a Doppler VOR
facility . We were sweeping the pre-made cables  that came with the
system and finding a lot of them bad. We cut open a few of the bad
cables and founnd the center conductor was not in the center of the
cable. All of a couple of hundred cables had to be remade and cut for
proper phase. The other grunt worker Dust Craig and I  became very
proficient at putting N connectors on RG-214 and using a vector
voltmeter.

Jimmie

>Thanks.

There's not much to say or show. The usual example is the common RG-6/u cable TV coax, that uses the solid center wire as the center pin of the F connector. By necessity, the center wire is rather stiff. There's also no way to immobilize the center wire as there would be no room for the mating jack. If the rotary razor blade wire stripper or half asleep tech with the wire cutters manages to nick the center wire, chances are good that moving the cable around will eventually break the center wire at the nick.

Crimp type BNC plugs are also susceptible in the same area. The difference is that the center pin is either crimped or soldered. The center pin is also supported by the Teflon insulator. However, if the coax is moved constantly, as is common with test cables, any nicks in the center wire will eventually turn into a break. This one is particularly insidious because it occurs inside the connector, where both ends of the break are supported in place, resulting in an intermittent, rather than a clean break.

Big fat center wires are not immune. They just have a different problem. When one of the heavy stranded center wires from RG-8/u style coax breaks at a nick, it's usually perfectly positioned to short to ground. In the common PL-259 UHF connector, the coax end of the break is not supported, resulting in a difficult to find, and impossible to see, intermittent.

In my limited experience, the tools that cause the most problems are the ones with the built in razor blades:
<http://www.mytoolstore.com/ideal/ide08-07.html>
<http://www.mytoolstore.com/ideal/ide08-06.html#coax>

<http://www.mytoolstore.com/ideal/ide08-08.html>
<http://www.fab-corp.com/product.php?productid=1665&cat=281&page=1>
<http://www.hyperlinktech.com/item.aspx?id=879>
(Note the huge variation in pricing)

As long as the blades are sharp they work just fine. However, when the blades get dull, the user tends to bend the cable to assist in the cutting, which sometimes results in a nicked center wire. Cleaning up the stripping job with a pair of diagonal cutters also causes problems. Stripping is also difficult with Teflon insulated wire and non-wicking insulation (marine coax), where the dielectric materials are bonded to the conductors. The best way to strip these materials and to be sure not to nick the wires is with a thermal wire stripper.
<http://www.teledyneinterconnect.com/products/wire_strippers/wirestrip.asp>
I got lucky and ended up with pile of these from some aerospace surplus outlet. Very handy. Just take care not to breath the fumes.

However, if you're working with LMR-400, LMR-600, or larger, the blades of the thermal stripper cannot expand wide enough to fit the coax cable. Therefore, I suggest getting the correct Times Microwave EZ-Strip coax stripper for these cables:

Before retirement, many of my instrument designs had to work in high-temperature, corrosive environments, so I frequently used PTFE* insulated wires. I purchased one of the Teledyne thermal strippers and was VERY pleased with its operation. The next year I found one for sale at a hamfest for $5. I snapped it up immediately for home use. If you work with small gauge wires, and especially with PTFE insulated wires, I strongly recommend these units.

We have a couple at work and I think they are the greatest thing since
sliced bread and I wanted one for home use but didnt have quite the
need to match the cost.

Not being lucky enough to find one for $5 I ground a notch in a hose
clamp and fastened it to my soldering iron. It works well on just
about anything except PTFE.

I tried doing that with a 4cx250 once.  Never got it to work. Looking
back on it I should have mounted the base of the tube to the paint can
lid and hung it in the bucket upside down.
Hmmm, might be something fun to try this winter.

Thanks much. I checked my email this morning and found one person asking me to sell them one of these strippers, and two more asking questions about their operation. Apparently, there's some interest so I'll post my answers.

1. You can find various thermal wire strippers on eBay, usually for peanuts. For example:
<http://cgi.ebay.com/ws/eBayISAPI.dll?ViewItem&item=320323912948>
The problem is this style of stripper is only suitable for small diameter wires and small diameter coax cables. RG-6/u can be done, but it's tricky. Make sure you get the long jaws if you want something fairly universal. The problem is not getting the jaws wide enough. It's preventing the end of the coax cable from getting jammed into the narrow part of the jaws.

2. Teledyne does make the TW-6 model, that's made specifically for coax cable.
<http://www.teledyneinterconnect.com/products/stripall/models.asp>
I have several of these. We used these in a production environment to strip RG-188/u with PTFE wrap insulation and dielectric. We tried using blades, but thermal stripping was far superior.

3. Note that most models come with various forms of power control. This is not mandatory, as I have become quite proficient at timing the push button for temperature control. However, if you want to avoid overheating, burned out tips, and meltdowns, make sure you get the temperature control. If the tips glow red, it's far too hot. Adjust the operating point with an infra-red optical thermometer,

4. You can make your own thermal strippers from a length of nichrome resistance heater wire and a small soldering iron. Remove the copper tip and replace with a piece of nichrome. I've also seen a production machine made from a plastic bag cutter/sealer and another from a foam cutter. A low voltage filament transformer and a variac can also be made to work. Obviously, some experimentation will be required, but it will get warm and eventually work. Nichrome wire is available at most hardware stores for repairing heaters, toasters, and telescope condensation prevention heaters. You will need to supply some spring tension as the wire stretches when it gets warm.

The problem with using wire is that it doesn't last very long. The large heating tips of the Teledyne strippers are sufficiently massive to survive for years of constant production line operation. I can't say the same for using wire.

I suspect that one of the handheld battery operated soldering irons, could be morphed into a thermal wire stripper by replacing the heating tip with a nichrome wire.

That's because everyone in the industry steals them, takes them home, and uses them for the rest of their life. They're hard to find.

>However, I am having visions (sometimes I do that, yanno', must be the
>60's or sumthin'? <grin>) I see myself grabbing a small brad in a pair
>of needle nose, heating it red hot and running it about the diameter of
>a wire--in a pinch.

Won't work. There's not enough thermal mass in your hot brad to do the job. The hot brad will need to hit the coax braid, or wire center conductor, in order to thermally cut through the insulation. Copper is a very good thermal conductor. As soon as the hot brad touches the copper, the heat gets sucked out of the brad rather rapidly. It might work if you're careful or very fast, but methinks it's not very practical.

Of course, you can use a large block of hot aluminum or copper with a cutting edge, but that would be potentially dangerous and certainly rather messy if you mishandled it. Of course, you're welcome to try it. Have burn grease, Band-Aids, and a fire extinguisher ready.

>Replacing the high tech brad as necessary ... <straight face>

Incidentally, I got my experience with hot wire cutters (and burned fingers) at my father's lingerie factory in Smog Angeles. We made our own as the commercial versions were seriously overpriced. My childhood wasn't totally wasted.

Hey OM

I should has learned to play the guitar. Instead I got into
electronics built my first xmitter in '67 using a 6BQ5 xtal osc and
6146A final.
Everything was hot. I used series twist lock caps in the ps, B&W coil,
with aligator clip adjust, multi elmac plate and  tune caps, a tv set
power xformer, all that on a punched out 5x7x2 LMB chassis. Even the
Key was hot as I keyed the screen of the 6146A.

I am shuting down my shop after 40+ years of electronic repair services. Mostly tube type equipment.

I have several used transformers that could be used to make some tube type transmitters(low power). Also bunches of new and NOS tubes. Just bunches of stuff.

One transformer has 478-0-478, 50vac bias winding and a 5v winding for a 5u4. It wieghs in at 7 pounds and is a horizontal thru-chases mount. USA shipping only.

send me an email;

(((((richklestinez(at)charter.net)))))

with INVENTORY REQUEST in the subject line.

Thanks for your interest.

Rich

Hi all,

Over the past few years, I've had the opportunity to save some decent reference oscillators from being thrown away, by removing them from scrap boards. They're typically good stability (temp. compensated), and reasonably low phase noise. I have 10MHz, 20MHz and 100MHz, and a couple others. Some have a voltage control input. All are 5V (but I know some will work down to 3.3V), logic output (but "logic" means PECL for the 100MHz ones). I'd be happy to send one or two to folk who have a specific reasonably immediate need for such a beast. If you're interested, drop me an email to let me know exactly what you're looking for and why you want it. I'll let you know if you made the cutoff. I may ask for shipping costs if I can't figure out how to send them cheaply enough but packaged safely. The oscillators will be free to good homes, though.

Cheers,
Tom

I've never xrayed or took a 6L6M apart. However the 6L6M would have
shorter leads and different inter-electrode capacitance specs due to the
metal envelope and the shorter leads. Also the metal envelope might
lead to a lower max plate voltage rating due to the danger of arc-over
to the envelope (which is connected to pin 1 for ground/shield). The
glass envelope version of the tube has more electrical insulation in
this regard. The 1614 is a transmitting version of the 6L6M. Other
than being spec'ed for ICAS operation and *maybe* having additional
internal shielding it's identical to the 6L6M.

I recall an article on using a 4cx250 with water cooling.  Actually it
sat upside down in a pool of water which was allowed to boil off from
the heat of the tube.  Which means the tube didn't get hotter than 100
degrees C (until all the water boiled away).  This is known as 'vapor
phase cooling'.  Believe it or not you can cool a tube with STEAM!

>>>
>>> Dunno if it's been mentioned yet -- 2E26.  The 807 is _not_ a 6L6 in
>>> a different envelope -- it's quit arguably the 6L6's big brother, but
>>> it's got different ratings; it could probably be shoe-horned into a
>>> circuit designed for the 6L6, but you'd be missing out on about 6dB
>>> of final output power.
>>>
```

>> The 807 IS a 6L6G with a 5 pin base and the plate connected to the top.
>> The published ratings of the 6L6G look different than the 807 because
>> of their intended use. ICAS ratings for the 6L6G were never published.
>> Also the 807 has additional shielding and insulation over the 6L6G
>> that make it usable at higher frequencies and voltages than the 6L6G.
>> Most 807's have ceramic spaces to support the plate which are lacking
>> in the 6L6G. But make no mistake about it, the two tubes share the
>> IDENTICAL cathode, grids, and plate structures.
>>
>> The 6BG6G tv sweep tube IS an 807 with an octal base. It has the same
>> ceramic plate supports, but lacks the extra rf shielding.
>>
>> The 1625 is an 807 with a 12.6 volt heater and a large (same as type
>> '59) 7 pin base.
>>
>> The type 1614 is a metal tube based on the 6L6. It is a transmitting
>> version, and probably has additional shielding. Otherwise its internal
>> structure is the same as the 6L6 metal type.
>>
>> The type 1619 is sorta kinda a 6L6 with a directly heated 2.5v cathode.
>> Same metal bulb as the 6L6. Specs' are different due to the different
>> element spacing thanks to the filament cathode. This tube is often
>> triode connected to replace 45's and 2A3's in old radios with a socket
>> adapter.
>>
>> As a result the of the construction differences regarding shielding,
>> the 807 often would NOT need neutralization while 6L6G's and 6BG6G
>> tubes used as rf power amps do.
>>
>>
>> The 6L6GA was identical to the 6L6G except that the bulb shrunk from
>> an ST16 to an ST14 size. The 6L6GB was identical except for the bulb
>> changing again to a T14. The 6L6GC is a totally different bottle with
>> higher plate and screen dissipation and plate voltage ratings. The
>> 6L6GC was said to be a plug in replacement for the older 6L6 tubes,
>> but RCA kept the 6L6GB around for a while anyway. In fact a bias
>> re-adjustment was a good idea when replacing an older 6L6 with the 'GC
>> version if a cathode bias resistor wasn't used.
>>

I've done a lot of reading on this subject. Old QST's (from the '30s),
books about tubes, and I've smashed a few open (dead ones of course).
I also have a small collection of old tube manuals (in print and pdf off
the 'web).
BTW the 6L6 family tree is quite large and includes bottles such as the
7027/A (really a 6L6 with a bigger plate and TWO base pin connections

for G1 and G2). Most sweep tubes are descendants of the 6L6 (the 6BG6G directly and others indirectly). Other 'hifi' output BP tubes such as the 6550, and the 'KT' series are based on the 6L6 with larger elements for handling more power. The British have in interesting twist on the language. KT stands for 'Kinkless Tetrode' which refers to the lack of the dip in plate current as the screen voltage reaches the critical point of secondary emission in tetrodes. BP tubes are considered tetrodes since they lack a third grid, but those BP tubes with beam deflection elements should be considered 5 element tubes. (Not all BP tubes have the deflection plates. The critical parts of the BP formula are aligned turns on G1 and G2, critical spacing between G2 and the plate, and optionally deflection elements to focus the electrons into sheets. Having a plate with 'catch pockets' such as on the 4-400 works as well as the BD elements.)

My neighbor gave me one of those 5 tube AM BCB radio kits back when I
was a kid. It was part of an electronics correspondence course he was
taking. The idea was to put it together breadboard fashion on the
schematic then when you got it working move it to the chassis. I
thought it was cool just keeping it on the breadboard and hauled it
around for years until it finally got stolen out of storage about 20
years ago. Over the years I had tested several mods on it. HF
converters, adding another IF stage, a BFO, Q multiplier and reworked
the series filament string for parallel operation. I'm sure if it was
still around I would still be tinkering with it.

Jimmie

I didn't build a transmitter when I got my Novice License (in my teens), though I did start collecting parts to do so. I was going to build a rig using a 6GK6 oscillator and an 807 final. But, on Washington's birthday I went down to Harrison's in NYC for their big yearly sale. They had a stack of Elmac AF67 transmitters for about $15 each, so I got one. I had to build a power supply for it though. This I did using a junk salvaged from old TV sets found curbside on garbage pick up days.

I used to ride around the neighborhood on my bicycle looking for thrown out TV sets. I carried enough tools with me to pull a chassis out of a cabinet and lug it home. Then I'd tear it apart in the basement and keep the goodies.

Seems all of those AF67's had the same problem, burned out modulation transformers. But they worked great on CW with crystal control. Some of them also had bad VFO's.

Years later when my brother got his novice license we found him a used Lafayette HA350 receiver and I built him a two tube transmitter. Actually I used parts from my now defunct AF67 stuffed into a large minibox as a chassis. It used the 6GK6 (from the junk box) and a 6146 in the final (from the AF67). I wonder if he still has that transmitter lost in his basement? I might want it (and the HA350) back.

Anybody have a BFO coil from a BC454 receiver?
I have a homebrew receiver project in mind using some of the
1415 khz IF transformers out of one of these but I don't have
the BFO coil.

======================================
This being a homebrew NG.......would it not be possible to make the BFO
coil ,or is it a RF transformer , yourself ?

Huh? No way... you MUST have non-linearities to make a doubler.

I do have a few extra 1415 khz if transformers so I could probably
convert one into a bfo coil if I can't find the real McCoy.

Hi all,

I have been talking to Colin Horrabin, G3SBI, and we spoke about the
good work Meirtein Bakker, PA3AKE, is doing on his high performance
analog front-end receiver using the H-Mode Mixer.
Martein is a very good research engineer and amateur radio. With his
knowledge, determination and attention, using homemade test equipment
and a W&G spectrum analyzer he has identified a design problem in the
AD9910 which will probably also affect the AD9912 and other recent DDS
chips by ADI. Colin was able to talk to Analog Device high speed DDS

group in North Carolina. There was a great deal of reluctance to accept Martein's findings. Eventually they were able to duplicate his results and they were very grateful to Martein because the same mistake will not be made in their new designs. We have a very low phase noise with ADI 9910-12 DDS but we are discovering AM noise !!!! a problem not present with the AD9951.

As Colin stated, the remarkable thing is that it has taken an amateur radio state of the art receiver project to identify this and it has not been found by Analog Devices big customers with all their high tech test equipment.

The bad news is that it is unlikely there will be a chip revision, even though the fix is simple unless there is pressure from a major customer. Maybe this is a good pressure some of our colleagues could apply to ADI from their engineering key positions.

Analog Devices is a company we all have a lot of respect for. The high speed DDS chips are a major technical achievement and are useful to our hobby as Martein will show. During chip development the design team probably paid too much attention to results from their high tech measuring equipment when by design it rejected a device parameter they should also have been looking for.

Martein has just published an update to report on the evaluation of the AD9910 DDS chip to be used as the DDS-Local Oscillator that complements the Down Conversion Frontend. The research regarding the AD9910 and especially its noise characteristics is finished. Those interested can visit his web page:

http://www.xs4all.nl/~martein/pa3ake/hmode/index.html

73 and with the occasion Season=92s Greetings

Gian

I have some door kick panels, some brass and a couple of Al ones. I have used these before to make enclosures but in the past I always cut them with a reciprocating saw then did a lot of filing to get the edges straight and pretty. I was wondering if I could cut these using my table saw. The motor is sealed so I don't have to worry about getting metal shavings in it. Anyone here ever done this before. If so what kind of blade did you use? Were there any special techniques you applied?

It seems like this would save me a lot of finish work if I could do it.

Jimmie

I have used high speed small table slitting saws to cut small pieces of non-ferrous; for larger projects, I have used a table saw, radial-arm saw or circular saw, with the blade reversed (old plywood blades generally). Except for the large kerf, I get straight edges. For most projects however I resort to the hand hack saw and file ;)

One can make a high speed slitting table saw from a lateral mounting of a dremel tool; use multiple emery cutoff wheels on the arbor or a diamond wheel.

Michael

I've heard of people cutting non-ferrous metal with a table saw.
If the metal is not too thin it should work, thin metal may curl up and
bind in the saw, or worse go flying off the table!
If you must cut thin metal back it with a piece of thin hardwood.
```

I've also heard of people mounting the blade backwards so the teeth face away from the work to cut aluminum. Not sure how this helps, but others say it works.

Perhaps I should have said 'backward' rather than 'reversed' as the latter may imply reversed rotation. Mounting the blade opposite to its normal orientation is what I meant and that has worked for me on light gauge

metal. For thicker Al and brass, I have used the dremel slitting saw
method.

Michael

I have cut hard aluminum using a table saw with a tungsten carbide blade.
You have to be careful to feed the work slowly to the saw if you want
smooth edges. SAFETY GLASSES OR GOGGLES ARE A MUST!

73, Dr. Barry L. Ornitz WA4VZQ

All tubes (and transistors, etc) have non-linearities (if the transfer=20
characteristics are non-straight lines) if that is what you are talking=20
about.

However, I have observed output on a scope of second harmonics (and, yes,=
=20
the time base was set right and auto-self triggering) and the=20
amplifier was running no higher than Class B. You should actually try this=
=20
yourself and see for yourself. Tune the output to the second harmonic and=
=20
you will see grow out of the vally new "peaks" corresponding to that=20
second harmonic.

I don't know what the solid state gear is doing, but from many schematics=
=20
of the vintage tube gear I'm familiar with show, and measure, biasing for=
=20
linear operation, even in stages meant to multiply frequency.

>
>Huh? No way... you MUST have non-linearities to make a doubler.

Actually you do not need any nonlinearity to make a doubler (quadrupler, =
etc.).

Assume you have two Class B (or AB) stages that are driven in push-pull. =
 The outputs are connected in parallel.  And to make things even more =
linear, let each stage have a resistive load.  Each stage will produce a =
linearly amplified (but inverted) version of the input signal FOR THE =
```

POSITIVE HALF of the driving waveform only. Being driven 180 degrees =
out of phase with the input signal, the second stage will produce a =
linearly amplified but (again inverted) version of the input signal FOR =
THE NEGATIVE HALF of the driving waveform. Both outputs will have a DC =
offset of the plate (collector, drain) voltage.

The resultant waveform with the outputs in parallel will look like much =
like a full wave rectified version of the input signal subtracted from =
the plate voltage. To express this mathematically, let the input signal =
be expressed as:

Vin =3D A sin(wt)

Now let the voltage gain of each stage be "-k" and the plate voltage be =
"B". The resultant waveform of the two stages connected in parallel =
will be:

Vout =3D B - abs[A*k sin(wt)]   where "abs" is the absolute value

Vout =3D B - A*k sin(wt)   for   0 < wt < Pi   and
=3D B + A*k sin(wt)   for   Pi < wt > 2Pi or alternately =
for -Pi < wt <0

We can then calculate the Fourier series of this waveform to determine =
its spectrum. I will not present the calculations here as it is too =
difficult to show the integration over defined integrals using only =
plain text (and I doubt many readers will have math fonts anyway). If =
you wish to see the math for the Fourier series for a number of =
functions, read:
http://www.maths.qmul.ac.uk/~agp/calc3/notes2.pdf or
http://www.physics.hku.hk/~phys2325/notes/chap7.doc.

Vout =3D B - 2*A*K/Pi * [1 - SUMMATION {2*cos(nwt)/(n*n - 1)] for =
n=3D2, 4, 6, 8...

Note that the original frequency has been eliminated and that only even =
order harmonics are present, and that the amplitudes drop off quite =
rapidly. For example, the fourth harmonic will be one fifth of the =
second harmonic.=20

For those that need a simplified explanation of Fourier series, Don =
Lancaster wrote a good article that can be found at:
http://www.tinaja.com/glib/muse90.pdf. I always thought Don had a ham =
license but I could not find one.

In a real implementation of this multiplier, a tuned circuit would be =
used as the plate load. The Q of this tuned circuit will assure that =
only the second harmonic is present in the output. The two stages would =
need to be well balanced if cancellation of odd harmonics and the =
fundamental is required.

73, Dr. Barry L. Ornitz WA4VZQ

```
POSTSCRIPT:=20

Now let me describe how it is possible to produce ONLY the second =
harmonic.  Instead of using two Class B or AB stages, it is possible to =
use triodes operating where their plate current is proportional to the =
square of the grid voltage.  Driving the two such stages in push-pull =
with the outputs in parallel with a resistive load, the output waveform =
will be:

    Vout =3D B - A*A*k sin(wt)*sin(wt)

Using a trigonometric identity {see:
http://en.wikipedia.org/wiki/List_of_trigonometric_identities},
  =20
    sin(x)*sin(x) =3D sin(x)^2 =3D 0.5[1-cos(2x)]

thus    Vout =3D B - A*A*K/2 + A*A*k/2 cos(2wt)

This shows that only the second harmonic is found at the output.=20

Class B or even Class AB in the circuit you described are non-linear.
Try that circuit
with Class A biasing.

All that is really required is that the active devices have a different
gain with positive input signals than with negative input signals.  This is
easily achieved with Class B and Class AB stages.  As long as both stages
are identical the fundamental and odd order harmonics will cancel.  You are
```

correct that with two Class A stages where the gain is identical for either polarity of input, the output signal will perfectly cancel. To make the method work here, you could synchronously switch the input signal between two perfectly linear stages. My point was that a full-wave rectified signal contains only even order harmonics.

In the real world, as Stray Dog pointed out, ALL amplifier stages are nonlinear to some degree. The reason that Class AB and B amplifiers are considered linear RF amplifiers is that the tuned circuit on the output supplies supplies the "missing half" of the waveform. Without the tuned circuit, harmonics of the 2nd, 4th, 6th, etc. order as well as the fundamental are present. Odd order harmonics are only found if the gain is nonlinear for positive input signals. The tuned output stage passes the fundamental and suppresses the harmonics.

Thanks for pointing this out, Bill.

    73, Barry WA4VZQ

You mean to tell me that you take a clean sine wave... pass it through... say a single-ended class A amp... and you can put a tank on the output of that amplifier... and tune for a harmonic? You will get nothing.

Ima seriously looking at cooling with negative ions, I've seen an article once before in Popular Electronics or Radio Electronics.

But on further researching I found this: "If a gentle stream of charged air is directed at a red-hot metal object, the stream of air will cool the object as if its velocity were around 50MPH! Charged air causes anomalous cooling of hot objects and anomalous heating of cold objects.

at this site: http://amasci.com/freenrg/iontest.html

So then I'm using a bug zapper xformer, at about 5,000 VDC. At 10,000VDC it will blow out the flame of my BIC lighter. At these potentials how should one measure the temp?

Except for that High Voltage sizzle it's pretty darn quite.

Fine-toothed circular saw blade made for cutting metal works wonders
on not just aluminum and brass but also many hard plastics.

You will probably not find the optimal blade at your local home depot
or hardware store. Check out mcmaster.com

If you can clamp the material or build a custom fence to hold down
thin material you will greatly reduce the vibration and noise.

Ear and eye protection is a must.

Believe it or not, I have seen aluminum machining done with a 2 or
2.25 HP electric router on long (20, 30 foot) bars for cutting slots
etc.

Tim.

I'll just add a footnote. When I actually built a few "buffer" amplifiers (tube jobs, 12BY7s, 6AG7s, etc), and for the hell of it, hooked up my scope (an old Tektronix solid state scope with one microsecond/div timebase, max) and actually looked at the sine wave (it looked 'nice' by the way) and then tuned the air variable through both the fundamental or the second harmonic (and I'm talking about 2-3 mHz signal source), I was amazed to be able to easily see the extra "peaks" come out of the "valleys" of the fundamental and I'm running these tubes at zero bias, low plate voltage, too. Look in the tube manuals for any class C tube and they talk about -50 to -70 v, grid negative wrt cathode. Class B and below talk about negative bias much lower but still pretty negative.

Like I said, I was surprised. This _should_ be discussed in the ARRL handbooks (maybe it is, but I couldn't find it [maybe I didn't look hard enough?]) and it would be worth 1-2 pages to show everyone what these signals have in them.

Here is another goodie (true story). R-390 local oscillator (runs 2.4 to 3.4 mHz, single 6BA6 tube). Had it set to about 3 mHz and looking at that "nice" (I have no harmonic meter to measure distortion) sine wave on the scope, and I "loaded down" the oscillator output lead with a tuned circuit and tuned that circuit to about 6 mHz. Guess what? Got double the number of peaks on the scope, just as with the linear amplifier. All calculate out on peaks vs time base divisions. So? Does anyone want to suggest that having the output LC circuit of an LC free-running oscillator tuned to double the frequency of the LC circuit is making it "oscillate" on its second overtone? ;-)

Yeah, I checked resonant frequencies with a GDO on all this stuff, too. I'm not making any of this up.

For the record, I also have an old Knight Kit RF oscillator (100Kc to 400 mHz on 3rd harmonic) and put that into my scope and the waveform looks like crap (but you can pick up the signal on a SW receiver set to where the scale matches the frequency of the oscillator). And, the shape of the crap changes from one end of the band to the other. Also have an old HP audio oscillator (high quality stuff) and it puts out a _very_ 'nice' sine wave no matter where in the range you set the dial (one Hz to 200 kHz).

73 all,

For thinner panels I use a large paper cutter that I reinforced the
hinge mount. This also cuts larger circuit board. For smaller circuit
board I use a tile cutter I picked up at a garage sale for a buck.

> nothing.

Class A means that plate current is flowing throughout the entire cycle of the input wave with the tube operated between cutoff and saturation. It says nothing about the linearity of the tube's transconductance (plate current as a function of grid voltage). With real devices, the transconductance curve is ALWAYS nonlinear to some degree, producing distortion (and harmonics). As you decrease the drive to a single-ended Class A amplifier, you are working on a smaller and smaller portion portion of the transconductance curve which decreases distortion. In the limit where only an infinitesimal part of the transconductance curve is used, you will get no distortion and no harmonics. Of course, in this situation the tube produces NO output.while drawing current from the power supply.

The scheme that I was talking about, known as a push-push doubler, generally uses the tubes operated in Class B although AB operation will work too, but it produces less harmonics. The real advantage of a push-push doubler is that odd order harmonics and the fundamental cancel out, making the resultant waveform easier to filter.

>>>> =A0Actually you do not need any nonlinearity to make a doubler
>>>> (quadrupler, etc.).
>
> You mean to tell me that you take a clean sine wave...

You might want to consider qualifying your thinking on this by setting a=20
specification for harmonic distortion (in other words, you might need to=20
consider how much of that "clean sine wave" signal has other components=20
in it, including non-harmonic componentes)

  pass it
> through... say a single-ended class A amp...

You might also want to consider, here, too, how much harmonic distortion=20
THAT class A amplifier also causes which makes a contribution to the=20
output.

  and you can put a tank on
> the output of that amplifier... and tune for a harmonic? You will get
> nothing.

You might even more also want to consider that any tuned circuit will pass=
=20
energy not at the resonance of that tuned circuit.

You would probably contribute to your own enlightenment if you actually=20
did some real experiments on this. It does not take long to do.

Back when I was an undergraduate student with major in physics (BS, 1966),=
=20
I worked in a Mossbauer Effect spectrometer lab and we built most of our=20
equipment (dual delay line pulse amplifiers, regulated DC power supplies,=
=20
repairing survey meters, etc) my boss had me build a waveform converter=20
that used a network of resistors and diodss to convert a sawtooth waveform=
=20
to sine wave and he was doing this because the book he got the circuit=20
from said that there would be less than 1% harmonic distortion and he was=
=20
interested in that specification for the spectrometer drives and all of=20
our commercial high quality signal generators were worse in that=20
specification, particulary at the very low frequencies we ran the drives=20
at (less than one cycle per second).

So, you have to define what you mean by "clean sine wave." But, I'll also
say that, no, you will not get nothing if you tune to the second harmonic
and have a linear amplifier (unless, maybe, you have a _perfect_ sine wave
and a _perfect_ linear amplifier [the rest of you guys might want to commen=
t
```

on this <yeah, I know about Fourier analysis, too>]).

I have used composition blades for aluminum/steel/copper sheet, angle,
tubing and rods with good luck.

Wear eye protection and hearing protection!

The cut edges will be sharp, file or sand until smooth.

Well, I tried using a carbide tipped blade to cut some thick aluminum
plate and will never do that again. There is an extreme tendency
toward kick back. The same blade performed well for cutting Al tubing
in my radial arm saw. I think the problem is mostly becase of the way
the angle at which the blade is ground. Perhaps installing the blade
backwards may solve this problem.

Jimmie

> nothing.

Of course you will. No active device is perfect.

I decided to illustrate the fact that a single ended triode operated in Class A can produce harmonics. For a tube, I used a 6C4 (1/2 of a 12AU7) operated with 300 volts on the plate, a grid bias voltage of -7 volts, driven with a pure sine wave of 14 volts peak-to-peak. The high driving voltage was chosen to illustrate my earlier points, but the stage _IS_ operated Class A with the plate current between cutoff and saturation.

Since the "rec"groups are not supposed to have binaries in them, I placed the graphics as PDF attachments to a post entitled "Harmonics generated by a Class A stage" in the "alt.binaries.ham-radio" newsgroup. If anyone wishes to see these curves and their newsgroup provider does not provide this group, I apologize. I believe Google Groups may not provide binaries, so I suggest getting a real newsreader and a good newsfeed.

The first graph is entitled "Transconductance.pdf" and it shows the plate current as a function of the grid voltage. This data was obtained directly from the General Electric datasheet, ET-T1604 dated March, 1960. Since Excel stinks when plotting and doing calculations with data that is not best expressed in a bar chart, I used an evaluation copy of PSIPlot from Poly Software International (http://www.polysoftware,com) to generate the plots. {Real scientists and engineers never use a bar chart except when making presentations to brain challenged management!} :-)

The driving waveform and the resultant plate current waveform are shown in the graph entitled "Waveforms.pdf". The obvious flattening is due to cutoff being approached at the crest of the driving waveform. After all, the transconductance curve is not perfectly a straight line.

Finally, the spectrum of current waveform is plotted in the graph called "Spectrum.pdf". The spectrum has been normalized with respect to the DC output. The scale of the X-axis is slightly off but it was not worth my time correcting it. The fundamental is about 60 to 70 percent of the DC output, and the second harmonic is about 40 percent of the DC output. All higher harmonic are less than one percent of the DC output except the fifth. Higher harmonics are still greater than one tenth of a percent of the DC up to the _13th_ harmonic. Harmonics beyond the 14th are still readily measured.

In conclusion, even single ended Class A amplifiers generate harmonics. If a lower driving voltage were used, the amplitudes of the harmonics would be reduced, but the fundamental would also be reduced. Please follow-up to the "rec.radio.amateur.homebrew" newsgroup. Golden-eared audiophools will be ignored.

Did you bypass the cathode resistor or not ?

All active elements are more or less nonlinear, so if you need more or
less linear amplification, you need to use feedback/feedforward.

A non-bypassed cathode/emitter resistor will greatly improve the
linearity of a single stage.

At last - someone using the right tool for the job! Circular saw blades for non-ferrous metal cutting are specially designed to reduce the dangers of jammed blades and flying metal.

As well as having many small teeth, the front cutting edge of each tooth slopes slightly backward to avoid digging into the soft metal (known as "negative rake"). Also the top profile of each tooth is designed to remove the metal as small chips.

Even negative rake blades are not jam-proof, especially when cutting through tubing. Half-way through the cut, it becomes very easy to hook a tooth into the wall of the tube, and BANG - it jams. Larry is very right to be using a jig to hold everything very firmly.

Well <blush> let's not heap too much praise on my solution... someone else told me that this was the best/safest way to go. I clamp everything down before lowering the blade onto it.

One other trick I use to prevent a bunch of metal debris from flying around: my miter saw came with a cheap little "sawdust collector bag" that only catches about 50% of the debris. I remove that bag and attach my shop vac hose to the outlet from the saw. This works great and results in very little debris (I still wear safety glasses and work gloves, of course).

I also believe in the right tool for the right job too but when I saw
the $80 USD price tag on the right blade using the wrong one became
more appealing. Also I had read a magazine article on using regular
carbide tipped tools meant for wood to cut non ferrous metal. The
article is WRONG, Its dangerous. I finished cutting my panels with a
jig saw. I lowered the table on drill press to make it flush with my
table saw to make use of it's fench as a guide and installed a mill in
the press. I used the mill to plane the edges of raw cuts. Unless I
ever find the occasion to do small production run this will be the
way I do it from now on.

Jimmie

A few years ago someone gave me a box of tube sockets and some 5763s. I always wondered if they were any good. So I built up a sloppy little oscillator, running on 7038 and 22 out of 23 of them oscillated. It takes 17 seconds for a filament to warm up and the circuit to start putting out power.

Ok so what next? I notice in the tube manual, ARRL handbook 1966, that it has 13 watts plate dissipation. Wow that seems like a lot for a little 9 pin tube. So I built another stage next to the oscillator and a little pi network output and drove the heck out of it. Only got 3 watts. Then double checked the voltages since I was running on a variac and lo and behold I only had 5 volts on the filament so cranked her up where she should be and now getting 9 watts into 50 ohms.

Then checked the great W8JI website and see where he put some shaping into his DX60 to clean up the clicks so I looked at my output with a scope with my keyer banging away at the thing and ye Gads, a square wave. So now working on values of a grid block keyer circuit to round off the edges.

Fun stuff.

Added a socket for an 807. Wow, got plenty of drive !! 55 watts out with 600 volts on the plate. 2nd harmonic 45 db down, not too bad. Total money expended to date - $zero.

Anyone like to do something similar? If you need a 5763 and socket just let me know. All I ask is you to really use it, not just throw it in the drawer for some day in the future.

Oh by the way. This is just posted to homebrew, don't need to cross post it to the other newsgroups, too much of that going on. Pick the group that it belongs in and they will find it if they are interested.

73,
Rick K2XT

  I just spotted a local xmas advert, for a Infra-red Thermometer   for
~$25.00
Just the ticket for measuring these ticklish situations !
At that price I am tempted !

I did the same experiment that he did (6C4) only ran the cathod at
chassis, and grid through an RF choke, and 100 vDC on plate, and drove at
about 1/2-1 volt and that is zero bias, no need for cathode cap bypass, and
I got gain and second harmonic.

I'm still waiting for any "expert" comments from anyone who would care to
speculate on the contributions, from oscillator harmonic content vs
contribution from harmonic distortion in the amplifier.

Hey OM

your right of coarse I seen 'em at harbor freight tools also. I just rememebered the one I was trying to think of is ultra sonic sound used to measure tempurature. Something I would take a piezo transducer or tweeter and detect the temperature that way.

> Nonsense... please read the definition section at
> http://minicircuits.com/pages/pdfs/doub9-2.pdf

You are grasping at straws trying to defend your beliefs. Their definition only applies to their products. You should have read the entire article. If you consider the single discontinuity of an ideal diode at the origin as nonlinear, then you are correct. In practice, two Class AB or B amplifiers, operated over their most linear region (each individually producing harmonics and intermodulation over 40 dB down from the fundamental), can be used in a push-push configuration to produce even order harmonics. I believe "Stray Dog" and I both have shown that single ended Class A amplifiers DO produce harmonics.

The Mini Circuits "doubler" is, I believe, essentially a full wave rectifier using Schottky diodes. If the diodes were ideal, i.e. had no highly non-linear region at low voltages, there would be no fundamental output or odd order harmonics. From my earlier discussion of full wave rectification, perfect diodes would produce the fourth harmonic 14 dB lower than the second harmonic, and the sixth harmonic slightly over 7 dB down from the fourth. The Minicircuits device produces at its output the fundamental and odd order harmonics in addition to the desired even order harmonics. It also requires a drive level of between 0 and 20 dBm. Too low a drive and the doubling action disappears; too high a drive and the amplitude of the higher harmonics increases (until the device burns out).

Some further research into the push-push doubler reveals that two sharp cutoff pentodes would do a better job than triodes for this application. Also junction field effect transistors follow square law characteristics over a fairly wide range making them ideal in frequency doubler operation too. It is also possible to nearly achieve ideal diode behavior with the use of very high gain amplifiers with feedback through the diode. See the following Intersil ap-note for details:
http://www.intersil.com/data/an/an1114.pdf.

My post of the graphs has not appeared on the "alt.binaries.ham-radio" Usenet newsgroup, even on my nntp server which still insists that the newsgroup exists. I'll try again using "alt.binaries.radio.misc" this time. My thanks go to "Stray Dog" for his efforts in also experimenting with a single ended 6C4 triode.

My cousin runs one or did. He is/was a civilian employee at a naval base, he may be retired now.. I think he spent more time cutting parts out for custom cars than anything else. I remember the first time I saw the thing was in the early 80s and the computer that ran it took up 3 or 4 rack cabinets and data for the pattern was put in on mylar punch tape. The last time I saw it there were just a couple of PCs. He has even used the thing to cut automotive glass. Slices through it like the proverbial butter. There were rumors that Santa may bring me a plasma tourch set this year but I don't think its going to happen. He already remodeled my bathroom.

I learned many years ago that even non-binary newsgroups _can_ carry
attached files (in any format), but then later learned that ISPs can
configure their newsservers in ways that can prevent you from making a
post with an attached file. I discovered that when a post I tried to make
with a new ISP gave me an error message. It is possible that you have an
ISP that somehow prevents either/or the body and/or the attached file from
being posted either dependently or independently from each other. And,
tech support people don't understand this, and sometimes even the geeky
whips who are sysops don't understand it, either.

You might actually do better if you can set up a "personal" web page and
just load the jpeg or gif files with associated URLs.

```
    My thanks
> go to "Stray Dog" for his efforts in also experimenting with a single ended
> 6C4 triode.

Thank you for taking the time to read about my "discovery" and making an
acknowledgement. But, most of the tube transmitter schematics I ever
looked at for driver/buffer/multiplier stages sure looked like they
were running linear bias voltages on the control grids instead of
class C biases. And, it was quite an experience to see, on a quality
oscilloscope, that second harmonic come out of nothing as the air variable
capacitor was adjusted for the second harmonic frequency. And, the S-meter
on the receiver, tuned to the second harmonic frequency, also bumped up a
few S units, too, at the same time.

Hehe, no we do still have mail, though the level of service is dropping
rapidly :-)
I was just guessing, that shipping would be too high to make it realistic.

Best regards
Ebbe

About 5 or 6 years ago I think the government must have dumped its
```

supply of 5763s since they started showing up by the thousands, 1980s manufacture. Since as a kid I had seen lots of articles that used them, I quickly bought Too Many. I think everybody I know has at least 25 and often 100. Since then I've donated some and sold some and used some. It's a very nice little tube, and should last forever (+/-) in oscillator or QRP service.

Very interesting to hear how much difference the lower heater voltage made. It's tempting these days to just make up a 6.3VDC regulator and be done with it.

73,
Mike, KK6GM

Hey OM:

I have a zapper field strength meter and even on the most attenuated setting I read a 400W microwave oven form 100ft away. Now if that thing lites up an NE2 bulb outside the cabinet then you better worry. The guts of a microwave oven is no faraday cage. You want a real faraday cage did you try tossing it in the 12 ft section of a built in swimming pool?

> favor the harmonic from the crystal. (Stop me if I'm wrong already...)

You're wrong already, kinda.

Most of the schematics that I've seen from back then have the crystal oscillating at it's fundamental. If the energy extracted from the oscillator is at twice the crystal frequency it's because of harmonics generated in the tube.

I don't have a lot of reference material to look at, but I don't think that using a crystal's overtones to generate RF really picked up until the 50's (it was probably done during WW-II, but I only see it put forth as a common method starting with my '50's ARRL handbooks).

> But in a doubling amplifier stage am I counting on having enough
> harmonic content at the input or am I creating the harmonic with the
> non-linearity of the amplifier?

You're creating the harmonic with the nonlinearity of the amplifier. A class C stage (which is pretty much assumed for CW transmitters) is very rich in harmonics, and the harder you drive it the higher the harmonics go. So it's pretty easy to get one to generate considerable energy at a harmonic frequency, which you then pick out with your tank circuit.

Ok, I'll buy that. One description I read of the tritet osc described
it as being an oscillator with inherent class c amplification, hence the
plate circuit being tuned to the desired 'harmonic' and the crystal is
indeed operating at its fundamental freq.

I want to interface the audio from the Small Wonder Labs PSK20 to the
mic input in the Toughbook CF27 laptop. The computer has no line
input, and I plan to use the mic input via the port replicator. The
Toughbook reference manual doesn't give any specs for the mic input.

The user manual does contain this caution:

"Use only a monaural condenser microphone (miniature jack). Using
an input source other than a monaural condenser microphone
may not allow audio to be input or may damage the equipment."

Reading suggests that an L pad in the 40-60 dB range is required, but
I would like to narrow this down before experimenting. Any experiences
using the Toughbook on PSK would be helpful.

Thanks, Tom, N3IJ

Agreed, for an AP, if 360 coverage is needed, an omni with downtilt
is an appropriate option.

Not for clients.

Microphone does work well if you have a decent one. Also has the advantage of being able to record both sides of conversations for logging purposes.

The inputs are usually 500-2000 ohm impedance and have a DC bias for powering the mic.

I have always used what is in the junk box to make the transition. The speaker output is fed to a low impedance audio transformer. It may be 8 ohm to 2000 ohm or 500-500 ohm or whatever in that range. Such things are easily obtainable at RS and other sources. The output of the transformer is loaded with a resistor of 1k-10 k and a series resistor of 100k or more feeds the mic input. This will usually reduce the input to mic level and the transformer will break up any common mode potentials between the chassis of the computer and the radio that tend to bring hum and noise. You will also see a flatter response than with acoustic coupling. You should be able to reduce the mic level in the mixer applet to normal level. You may have to play with the 100k and may need to shunt the mic input as well but you will find this by experimentation to get it right. A purist might also series the input with a 1uf to 10 uf capacitor to completely block the DC component but the series 100k should limit that sufficiently. Some experimentation could be done for more precise equalization if you still have time on your hands.

This should work with any sound card mode.

Anybody here ever build a passive grid linear amp?
That's where you simply terminate the grid of a tetrode with a 50 ohm resistor and just drive it directly. Svetlana recommended that configuration with their 4cx400, 4xc800 and 4cx1600 tubes, and it should work well with more commone surplus 4cx250's.

I was thinking of using a 4:1 or 9:1 balum and increasing the grid resistor value to 200 or 450 ohms to reduce the amount of driving power required. With the 4cx250 a peak grid drive of about 50 volts is required in class AB1. With a 50 ohm termination the driving power would be 50 watts, with a 200 ohm termination 12.5 watts, and with the 450 ohm termination 5.6 watts. That's actually just the power sucked up in the resistor, but the tube requires less than 1 watt of drive itself in class AB1. Some power might be lost in the balum, so maybe the actual driving power might increase by a watt or two. Since I wanted this to be a final for a QRP rig the larger terminating resistance looked like a better way to go. The only issue is how high can you go with the termination resistance and keep the tube stable without neutralization being required?

Yep, for Clients, I use 12dbi Panel Antennas, which are very compact and
provide the required F/B Ratio and gain, for each link.

I use Plastic Buckets turned upside down, that fit over a 1/2" Plywood
Base cut to just fit inside the open rim of the bucket. They make
Excellent RayDomes clear up thru 5 Ghz, and come in various sizes from
Pints, Quarts, and Gallons, up thru 5 USG.

Howdy,

I've only read about them. G2DAF wrote extensively
on pasive grid linears.

I think the ultimate value of grid resistor will
depend on the grid capacitance and layout parasitics.
The articles I've read use 300 Ohms as the grid swamping
resistor but with a 4CX250 450 Ohms might be possible.

Here is an article you may find useful.
http://www.radioamator.ro/articole/files/291_1.pdf

I have a bucket full of 4CX250B's and would like
to try passive grid someday. Please Let us know
how yours shapes up if you decide to build one.

73,
Grumpy

That's an interesting article. He shows no matching network between his exciter and the linear so there would be a 6:1 SWR with the 300 ohm termination, though a tube type transmitter with a Pi network might still be able to load into it. Deriving the screen voltage from the rf drive seems a hybrid method of doing grounded grid. I was thinking of an amplifier with normal bias and screen supplies which would reduce the drive required.

I have a pair of used 7034's (4cx250's with glass seals) but I have no idea how much life (if any) are left in them. My idea was to build an amplifier chassis that could be used to experiment with several tube configurations. I've found a source for a 400VA toroidal power transformer with two 550v and two 6.3v (5A) secondaries and a 120/240 v primary for about $65 postpaid. In a bridge rectifier configuration with a capacitor input filter using large capacitors it should yield about 1400 volts under load. This would be a suitable plate voltage for a single 811A/572B or a 4CX250A. With the bridge rectifier configuration the center tap of the HV secondary will provide 700 volts that can be regulated down to the 300-350 volts required for the screen of a 4CX250. One of the 6v filament windings would power the tube (unless I find some 4CX250F/G's which would require an extra 25v transformer) and the other winding could be used with a voltage multiplier for the bias supply (or drive another filament transformer bassackwards for that purpose).

So I could build up a power supply and tank circuit that could serve either configuration, and swap out one of two chassis; one for a single 811A/572B and one for a 4CX250.350/400A. The target amp would be between 150 to 250 watts output (a nice afterburner for a 10-20 watt QRP rig I'm thinking about).

The defining feature of a G2DAF amplifier is not the untuned passive grid input, but the method of grid biasing. It has no control grid bias and the screen voltage is developed by rectifying the RF drive.

Most passive grid tetrode amplifiers use conventional fixed bias voltages on g1 and g2. Commercial examples include the Alpha 91b/99 and the Australian Emtron range.

G2DAF's published articles on amplifiers are on my web site, and the RSGB historical collection still has his original receiver, transmitter and amplifier, along with many hand-written notes. The 2 x 4-125A amplifier that featured in his published articles still exists, but at some later time he had removed the screen rectifier tubes and converted the amplifier into a very basic grounded-grid configuration.

I really don't see any advantage in his circuit over a conventional zero
bias grounded grid amp, at least not with the 4-xxx series of tubes.
With the 4CX250 series it makes some sense since these tubes CAN'T be
run in zero bias grounded grid due to the fragile grid structure in
these tubes.

This should jump out at you with the proper circuit analysis. Just
analyze the circuit with a parallel tank load on the plate, and look for
negative resistance showing up at the grid. Your grid swamping resistor
would need to take care of the worst-case negative resistance.

Then spend a month tearing your hair out over parasitics that increase
the plate-grid coupling over and above what the data sheet says they are.

Hey OM:

I don't see plate grid coupling with a grounded screen and the cathode
at negative screen voltage? eh?

You only needed 20W of drive power and a single HT supply. I have one
using a pair of 813s, 10W from my TS-120 drives it to about 200W output.

It looks to be exactly the same layout as the one on Ian's site but has
had the valve rectifiers replaced with solid state at some time.

200W from a PAIR of 813's? You must be running them with less than
1.5KV on the plates. That's the problem with 813's, they don't live up
to their potential (pardon the pun) unless you run them with lots of HV.
  The point though is that in conventional grounded grid (all three
'grids' grounded) you still don't need a SG supply and the drive power
should be about the same.

I think he means that any feedback which would induce instability can be
translated as a negative resistance seen at the grid (all an oscillator
is after all, is a negative resistance generator).  And ANY tube
exhibits some degree of plate to grid coupling in the form of stray
capacitance between the elements.  Even Pentodes with two grounded (for
rf) elements between the plate and grid show SOME coupling (though in
the case of screen grid tubes the value is reduced to values of a few pf
or less).  The grounded grid circuit reduces the feedback even more by
introducing a phase shift as well, but some grounded grid amps still
need some neutralization (especially if you mess things up by putting 4
bottles in parallel.)

Ive seen one amp that I know worked using a 4cx250B using a 16:1
transformer. He used tha amp on 6M. I think he still added a little
capacitance to tune out some of the inductance in the transformers.
The best I remember he really didnt have to do this. He just did it so
he would see a perfect 1:1 SWR beteween the exciter and amp. I
modified an old 2X 6146 amp with tunned grid by ripping out the tuned
circuit and replacing it with a 200 ohm resistor. 5 watts was more

than enough drive.

Jimmie

Yes, that's what I meant. And if you're looking to figure out the
largest parallel grid resistance that will still effectively swamp out
the instability, I think that's the best approach to take.

In theory, any tube is going to have _some_ coupling straight through the grids. In practice its probably vanishingly small.

But for many tubes you'll have to spend a long time optimizing the
physical layout of the circuit before you have more coupling through the
tube than you have around it.

That's with 10W of drive (From a 10W radio) and 2KV on the anode,
maximum output is around 600W with about 40W of drive.  You can wet away
with over 3KV on the anode if you are careful.
If you introduce a 4:1 transformer on the input the drive required is
far lower.
I have a KW500 with a single 813 in grounded grid, it produces 40W with
10W in and is a bad load for a transistor TX (No tuned input as it was
designed to work with a valve TX).  With passive grid you don't need a
separate tuned input for each band so it keeps it simple.

So did Mouser assist you in the design, or put up money to market you splatter circuit? Do they get a cut of your business? Do they sell your junk in their catalog? Or is your only partnership just that you order parts from them? Do they even know what you order parts for?

Partner with Mouser, yeah right, just more telestar hype.

Commander... Like I said earlier... the dictionary defines partner as
"One that is united or associated
with another or others in an activity or a sphere of common interest."
I guess you're not able to comprehend that sentence. Not really
surprising. If you're looking for an argument... I only argue with
worthwhile adversaries... lol

Greetings,

CQ-TV Magazine published an article in several parts entitled "Modifying the Sony HVS2000 video mixer"
sometime before 1997, in issues 132 and 133 (years not known); I would appreciate scans of this
article from someone who has those issues.

Many thanks,

Michael

Thought I'd reply to myself after a bit more diggin online; I discovered an archive of CQ-TV issues online at http://www.batc.org.uk/cq-tv/archive/

I am downloading the two issues and will report if the article is indeed found within.

Indeed, it is there.  I was initially confused by the title of the
publication, expecting that it was an offshoot of "CQ Magazine" but indeed no,
it is a British ATV publication and thankfully fully archived at the above site.

On the off chance that a reader of this newsgroup has worked with the Sony HVS-2000 luma keyer and has the manual with schematics, I would appreciate some scans ;) (I am aware of commercial manual sellers online who list the service manual, one of which offers a pdf version; has anyone seen that one?)

Many thanks,

Michael

Perhaps Mouser should be informed of this claim to partnership. They
may very interested.

Jimmie

Maybe not "informed" but ask people THERE, at Mouser, what their=20
"definition" of _partner_ is and then tell them about this guy.

"Dictionary" definitions should not be confused with word usage within=20
contexts that alter the meaning of words. For example, the word=20
_sterilize_ has a different meaning in banking/finance compared to=20
microbiology.

In a business context, "partners"  generally implies that an ongoing=20
relationship exists by virtue of a written contract. If party A buys parts=
=20
from party B, and pays for those parts with money, that establishes a=20
provider-customer relationship, not a partnership.

I have their 2008 sept-oct catalog and "Telstar" is not listed in the supplier index at the end.

Does Telstar provide any kind of study data that defines what "maximum range from their rig" actually means?

And documents that the processor actually does something measurably beneficial at the receive end?

The last I heard a partnership required a legal agreement between two
or more parties agreeing to be parters. It may be a case of the powers
that be at Mouser asking themselves "Can I make more money off of
Telstar by doing business with or by taking legal actioon against
Telstar".

I once had a similar complaint lodged against me when I had my own
business because my sign and letterhead read ....serving in
partnership with a well known electronics supply firm. I manage to get
away with it because they had sent me a letter after I had opened my
account with them stating how they "anticipated serving in partnership
with my business". I had based my shingle on this quote.

Jimmie

There are no federal laws in the USA governing partnerships.
It may be covered by some state law where Mouser is incorporated.
The issue is trademark infringement. Something most companies
take quite seriously.

I hear you Jimmie, the simple fact is Brian uses google to cross post/spew
his product. As far as I know they don't give a flying rats ass about
usenet abuse.

I say no one is buying it anyway so let Brian carry on from his parents
basement. No harm no foul.

the problem is certainly guy seem to have a case of OCD concernign him
and he uses them to ppormote his product a nice way of making
lemonaide of that problem

Hi, I'm looking for an article that was in an old Practical Wireless
magazine about early to mid 50's it was about a simple two valve HF
transmitter, it was unusual as the chassis was made of Hardboard!! I'd
very much appreciate a scan if anyone can find it, or possible an idea
of the month and year of the article, thanks from Ron G3YUH...

Trademark infrindgement was there complaint against me. I was young
and more foolish than I am now and thought the little blurb on my
shingle would be funny and no one would even notice. They noticed and
didnt think my humor was that funny. For me it only took about 10
minutes and some black paint to remedy the problem.

Jimmie

In 1930's QST's it's not too uncommon to see neophytes warned that
crystals will often oscillate on something other than their marked
frequency. They didn't call this overtone operation, though.

BC-604's (WWII era) start with a ridiculously low crystal (400ish kHz)
frequency and multiply up but I think the reason for this is more to
do with FM deviation than anything else. ("Armstrong method"?) For
many decades, broadcast FM stations similarly started with low crystal
frequencies and multiplied up.

Tim.

They /might/ be suggesting that frequency can change with loading. I find
that some of the reference crystals I use are quite some way off their marked
frequency when given capacitive loading that differs from that recommended by
the manufacturers!

Some of the broadcast transmitters I worked on 25 years ago used this method for FM, and were /really/ difficult to line up! They also included complex circuitry for the required "pre-distortion" of the audio to compensate for the non-linear deviation you got out of a crystal oscillators. Some manufacturers tried to overcome the distortion issue by using phase modulation and the "right" audio curves, but these required even more stages of multiplication!

One of my earliest jobs as a broadcast transmitter engineer was to develop a PLL to replace the horrible multiplier chains in some of these transmitters. I used (normally) either half or quarter frequency generation, and used the last one or two multiplier stages. The CMOS PLL circuitry could be prone to bizarre effects with high field strengths, so they were built in sealed diecast boxes, and the lower frequency generation meant that the high power output stages were unlikely to couple back into the oscillator!

Bob

I went through two WTCP's. They worked ok, but eventually got
intermittent and would not stay hot. I now have a WES51/PES51 setup.
No more changing tips to change temperature, just dial it in. No led
display, but the dial is calibrated close enough. Also the soldering
pencil is lighter and less bulky than the WTCP was. Still I did like
the WTCP's all in one construction over the two piece (power supply and
iron stand) of the 'ES51. The Coper group has destroyed Weller. I
collect old Weller guns whenever I find them, the new ones SUCK.

Looks like something I found in my grandfather's car house. His was a
wood frame with copper sheeting. He said he built it a few years
before WWII. We cleaned it up and he fired it up and he lit up a
little light bulb so I'm figuring 3 or 4 watts. After that I polished
up the copper and really cleaned it up and fired it up one more time.
He ran a depot for the railroad and was always going to get his ham
ticket but never did though he knew morse code extremely well and
built several transmitters and receivers.

Jimmie

Another good source for gears and sprockets is www.smallparts.com  They
have lots of couplers, tubing, tools, etc as well.  Great source for
robot prototyping too.

Hey Ross:

I would think outside the box, forget a mechanical arrangement, use
the In line ganged to control relay switching.

And if you really want to go mechanical for some strange reason I'd
use a flex shaft. Bend a flex shaft 180 degress and viola'.
I too have thought about this very topic, for my amp I might try pin
diodes since I'm a not using GG.

Howdy,

I've managed several labs where we had dozens of WTCP stations in daily use.

The only problem I found with WTCP is the connector between the base and the cord. I usually remove the connector and hardwire the cord at the base. It causes the intermittent operation that you've decribed.

I couldn't agree with you more concerning the damage Cooper did to the Weller brand. Since they moved production to Mexico the quality control is nonexistant. Some of the design changes which I believe were intended as cost reductions were ill advised too. The old Weller soldering guns are indestructable.

At home I have a Pace soldering/desoldering station and a Metcal SMT station. I've no complaints other than the price.

At work we have a Hakko soldering/deslodering station and it's a real work horse. We also have a Metcal SMT station which is a bit fussy but it has been though hell and back. We just bought a couple Pace ST70 soldering stations for general purpose work. I think we will buy a few more, they're great.

It's too bad that Wahl quit selling Sterling soldering irons in the US. It's an odd little iron but I love it. Thirty years old and it's still the first iron I reach for in my shop. The original tip is perfect! I called Wahl about buying a second iron and no one there knew what I was talking about. The most clever feature is an aluminum washer between the tip and body of the iron. The difference in coefficient of expansion keeps the tip from seizing. It says made in England on the body. Google was no help... sigh.

73,

Grumpy

I have the Weller guns in 3 differant wattage ranges. I think this is one of each that they made. The 8200 I have is over 40 years old. The middle wattage gun is one that does not have the hollow nuts that screw into the end of the rods comming out of the gun. It is labled intermittent duty where the other 2 do not have this lable. It seems to be lighter than the smaller rated gun also. I don't use them much any more except to put the connectors on the PL-259.

I really like the guns for the bigger stuff the pencles will not work. I even used the 8200 on some of the older and larger PC boards.

I wouldn't be without my TCP, and spares are still available. Cooper
Tools in the UK give excellent customer support (though that's the
people, not the product).

Also take a look at the JBC range of soldering stations. They are beyond
my amateur budget but professional friends rave about them - they seem
to do everything the Metcal range can (and more) without the complex and
expensive RF heating. There's a video presentation at:
http://uk.youtube.com/watch?v=v2hLFmHTQvo

If you can post a photograph on a website, someone here in the UK may be
able to identify it.

I want to add a couple of deep discharge type batteries to my truck
for camping but how do I intermix them with the normal auto battery
and charging system. I was thinking about getting a charger meant for
charging batteries from solar panels and connecting the solar panel
input to the generator. A 20A charger cost about $50USD .This would be
very reasonable if I knew it would work as expected.

Jimmie

Howdy,

Thank you for the suggestion. I have posted an image of the iron at www.dwave.net/~twomules/sterling_iron.jpg

The manufacturer's name is Sterling and it's marked made in
England. The handle is tri-lobular in cross section. In the
handle there is a thermostat which is adjusted by means ofan
allen key and there is a neon bulb indicating the heater status.

I'd like to know if it's still being manufactured.

73,
Grumpy

Hello Jimmie,

I've used a relay to disconnect the auxilliary battery when either
the ignition is off or the auxilliary battery voltage is low ~11.5V.

There is a series diode and resistor in parallel with the relay contacts to bring the auxilliary battery back up slowly when the engine is running so the undervoltage lockout can reclose the relay and not dump the discharged battery on the alternator.

The automotive "ice cube" relays are good for this I've seen some rated as high as 80A.

Another refinement I did not try is a switch to override the undervoltage lockout so I could jump the vehicle off the auxillary battery. Perhaps the switch should be across the diode so the auxillary battery slowly charges the main battery?

73,
Grumpy

I used to have one of those, but it didn't last as well as yours did so it's long gone... along with all memory of the name!

Cross-posted to the good people at uk.d-i-y, some of whom have a bottomless memory about old tools.

Oh boy, do they ever! Thirteen replies already, all heavily laden with
soldering iron nostalgia... this thread will run and run.

One of them was even the right answer. From Jeff Layman:
>
>It's an Oryx 50.

Yes, that's the one I used to have.

>The name should be on the opposite side to that shown in the photo. Has
>interchangeable tips, is thermostically controlled, and the temperature

>

A bit of further Googling reveals that the Oryx tradename is still in
use, apparently owned by an Irish company named Portasol which now
specialises in gas-fueled irons (www.portasol.com).

I'm not familiar with the term split charge relay, but if it is what is referred to as a "Battery Isolator" then I actually like the idea. A good isolator will charge the starting battery first then it will take leftover power to charge the other battery. Combine this with solar power and you have a winning combination in my book.

I didnt think you could charge a deep cycle battery in an automotive system without damaging the battery. Its my understanding that car batteries are designed for a quick charge at realativly high current while deep cycle batteries require a long low current charge. To make it work thought you had to have a special charge regulator for the deep cycle battery.

Howdy,

Thanks Ian! Sounds like I'm out of luck on buying
a new Oryx 50. The writing on the handle is nearly
worn off. Now I can see why the people at Wahl didn't
know what I was talking about. I had it all wrong.

DOH! I Should have looked carefully at the stand!
It plainly reads ORYX and below that Reading England.
The name is moulded into the black plastic base but
not painted or ink stamped. I just never noticed it
before.

Wahl is still selling their battery powered soldering
iron. I used to own one of those until the nicad's
went bad. They're in Sterling Ill.

73,
Grumpy

Howdy,

What type of deep discharge battery do you mean?
Gell vs AGM vs VRLA vs Flooded battery generally
require different care.

I use low maintenance flooded deep disharge batteries
and charge them at 20% of their AHr capacity rating.
I'd have no worries about mounting one of these remotely
from the alternator (like in the trunk) and letting the
vehicle system charge it.

Gell or AGM I'd charge at 10% capacity or less. These
would require some current limiting circuit.

The volts per cell for full charge and float charge will be
different too. Though if you keep the battery between 80%
and 20% of full charge it's not an issue.

73,
Grumpy

If the RV isn't being used all the time the Battery chemistry is less of an issue. Deep cycles should be charged at roughly no more than 10 amps. and floated at 13.2 v. But if it is being cycled, the float value is less of an issue. You will need the long trip to insure it is up for the next stop.

If you are mounting the second battery under the hood, close to the charger, then it is best to use NR 10 or 12 wire for the charge line to limit the current and be able to disable the RV relay rather than leave it charging every day on long commutes. You will need to check the water more often.

I didn't see my earlier post, again DON'T use a solar charge controller as most regulate by shorting down the solar panel. If the system voltage is normal, nothing happens. If it should go high for any reason then it would simply burn out things.

I have had one since 79' and is on it's 5th set of batteries.  I replaced
the last set with 3ah NiMH and they never seem to go down now and has a
permanent place in my field case.

Im not sure but they are sealed 100Ahr batteries and the max recharge
rate is 10amps so definitly not FLOOD.
I have recharged them from my aux power connector in my truck bed but
this took a lot more care and effort than I wanted to give. Wife and
kid thought I was paying more attention to the batteries than them.. I
thought about feeding them from a constant current source. In this
case it would act more like a current limiter.

Howdy,

Ok, the minimum you'd need to charge these is a voltage and current regulated supply limited to less than 10A and 13.62 for AGM or 13.50 for gell (check the manufacturer's stated the float voltage). No more than 14.1V in any case.

The vehicle voltage is not much higer than this with the engine is running. It's possible to build a low drop linear regulator to serve this function. Linear Technology or Micrel should have an app note you can work from. This is the one device solution. You'll get a couple of hundred milliamps to an amp at 13.6V from as low as 14V maybe a bit less. Good for keeping the auxilliary battery topped off but not so good for recharging.

If you want faster recharge (which still won't be very fast since 120%-140% of 100Ahr is is going to take 12H-14Hr at 10A) I suggest a SMPS running off the vehicle battery it can charge the gell cell even when the engine isn't running.

Try National Semiconductor's Web Bench power design tool and roll your own with their parts.
http://www.national.com/appinfo/power/webench.html

For minimum recharge time a bigger SMPS (maybe a nice push-pull) is required. I might try a simple switcher boost converter or switched capacitor converter and raise the vehicle supplied voltage to about 24V at a few milliamps to bias a series pass MOSFET linear regulator. The output current and drop-out voltage are then only limited by the mosfet pass device(s) ... virtually unlimited! Though not as efficient as the switcher. Maybe a good idea to throttle back the current limit from 10A when the engine is running to a few hundred milliamps when it is not. Though even that's too much if the vehicle sits unused for too long.

Which causes me to ponder... you'll drain the vehicle battery unless the engine is running. Even at 10A charge current a full recharge requires a fair amout of driving! Perhaps it's better to plan on recharging the battery from "dock side" power and only trickle charge the battery from the vehicle to keep it topped off. One of the low drop regulator IC's set to 13.6V or a simple switcher(tm) would be all you need for that.

73,
Grumpy

Hey jimmie:

TI makes a really sweet ic for charging batteries the UC3906. Is the greatest IC since sliced bread for charging batteries. It took forever to charge my deep cycle marine battery like a110AHr. A straight charger it would take a week to charge 100% it's that last 15% that's the toughest. The UC3906 charged my deep cycle marine battery to full charge from dead in 10 hours. It's one of the greatest homebrew jobs I've done. I used it to charge a 110AHr deep cycle marine battery for my electric bike. I could ride 2 days on a single charge like $0.25 worth of electricty back and forth to work. 45 miles on a single charge.

Agreed! I designed a DC UPS power supply for Harris using the UC3906 to charge a 4Ahr gell cell for wireless pbx. The only down side is it requires some head voltage for the regulator, so it won't work well off a 12V vehicle system unless the engine is running and then not so great.

I still have two of those Harris power supplies one runs an HT monitoring a repeater and the other runs a scanner and a small transmitter. The batteries are ten years old and show little loss of capacity.

I think I am going to try charging it through a 10 amp constant current source. If it works the way I am thinking as the battery nears full charge the pass transistor should saturate applying nearly full generator voltage across the battery topping off the battery. Im thinking(hoping) that when this occours the voltage drop across the transistor may be just enough to yield nearly the ideal float voltage for the batteries.

The batteries normally power my heater and lights for my popup camper and a couple of radios that are mostly used for rx. With only an initial charge from the battey charger before leaving home I can camp about 4 days. With some additioal charging I am hoping to extend it another 2 oor 3 days. Since our trips usually include a few hours a day of driving I thought I would use this oppurtunity to top off the batteries. I have leaned against the idea of just running the engine for that purpose. The incandescent bulbs I am using in the camper are the main draw on the batteries perhaps going to LEDs would help.

Howdy,

The saturation voltage will probably be less than a volt, likely only a few tenths of a volt. When the vehicle is running the output voltage could be too high. A transistor that comfortably handles the ten amps is going to be something like a 2N2955 or 2N3055 there are curves on the data sheets that tell the story. As the current souce runs out of compliance and the current drops, the output voltage rises because the saturation voltage decreases.

There is an easy fix if you use a PNP pass transistor. Clamp the base at 13.6V plus a base emitter drop, say 0.8V, the output can't rise higher than the float voltage.

Better yet, use a TL431 to sense the battery voltage to end the constant current charge by reducing the bias and enter float mode. (The TL431 is a very handy device and cheap. Check the app notes and I'm sure you'll find many other uses for it.) Then either NPN or PNP will work, choose your poison.

I modified a junky old eight amp Kmart charger like this with a PNP device for charging the six volt battery in my tractor.

You'll need some sort of short circuit protection. During a short the ten amps times the supply voltage will be dissipated in the pass device. Could be a fuse or breaker or active protection. I left this out of my first attempt and the pass device didn't like being shorted for even a moment. Luckily I tested this before putting it all back together rather than finding out later on in a snow storm. The existing thermal breaker was much too slow.

LEDs would be a huge improvement.

73,
Grumpy

Saturation voltage my oh my. A simple DC to DC convertor on the gate
of a FET of like 4 milli ohm so no more Vsat. I've done it with the
UC3906 which is designed to charge lead acid. All you need is a source
that'll will handle all that current. All the tricks I've seen done
with lead acid charging constant current will fawk up ur battery
unless you know when to shut it off like the UC3906 does.
Maybe 3 TL431's as sensors and you can do it. But the UC3906 can
sense a shorted cell and will not charge the battery if there is a
shorted cell.

They gave it to you because Weller stuff is junk. I have seen more
Weller soldering stations fail then I care to remember over the years.
Don't spend a lot of time on it. Break down and buy a Hexacon station.
We have four here. They have worked flawlessly for over ten years with
heavy use.

Very Nice Tim OM!
A few years back I built an 80M rig from a 1928 QST design.
A bit bigger than that basically a T20 triode driving (I think)a 100TH
Colpitts oscillator and power amplifier. It worked surprisingly well,
put out about 60 watts and to mysurprise was much more stable that I
expected given a VFO putting out about 7 watts of RF!!!
Had few QSO's with it and then had to dispose of it when I retired and
moved house. I hope my fellow NZ Vintage radio club member is looking
after it! Of course they can be a bit lethal mine had 1Kv ht and apart
from an insulated front panel it was all accessible.

Of course you can roll your own switchmode psu from 12 volts to whatever
votage a laptop requires. That would be easiest. I've made a couple from
a circuit in the Aussie magazine "Silicon Chip" a year or so back and
they have worked well. The output can be varied from 12 volts to about
20 volts at up to 3 amps with no problems. I used mine to run a laptop
to drive my telescope in the field from a car battery supply.

Hello all,

Can someone explain to me the mechanism of how a VFO "pulls" during transmit? I have a transmitter circuit I've breadboarded, ugly construction style, and the VFO will pull up ~2kHz with the key down. The transmitter circuit is borrowed almost verbatim from the K1SWL SW40+ transceiver.

I've checked the following:

1. dropped off the driver and final amp circuit with no change in behavior
2. the tuning voltage to the varactor in the tank circuit does not change during keydown.

I know there could be several answers here. What should I be looking for?

Thanks to all,
Kenn
KA5KXW

Howdy,

Geez... I read this and it confused me. I haven't been sleeping much and shouldn't post late at night.

The easy fix is to use an emitter follower circuit where the the constant current load is connected to the emitter. If you put the regulator in the Positive side lead use an NPN.

In my instance the current regulator's pass transistor is in the negative lead so the heatsink is at the same potential as the vehicle chassis. No insulating hardware is required.

73,
Grumpy

Howdy,

If the supply voltage to the oscillator changes, even though the tuning voltage is stable, it may chirp or pull.

If the change is slow look for thermally induced changes like
You may not be able to feel this change with a finger. Applying a bit more heat to suspected parts might indicate the culprit.

Also look for changes in the voltage on large capacitors. It wouldn't be unusual for bias voltages to change when the oscillator starts up. An extreme case of this is squegging.

There could be many culprits:

Check the supply voltage to the oscillator. Does it change when the key's down? If so, try better supply regulation to the oscillator.

Does anything get warm either in the oscillator or nearby? If so, you've got thermal problems - changing the layout may help, or correcting the thermal drift with temperature-compensating components (I used to use thermistors to change the bias on varicap diodes to do this).

Does the loading on the output of the oscillator change at key down? If so, you need a better buffer stage. I usually use FET buffers for very light loading (high input impedance).

If all else fails, you're going to have to either rebuild the oscillator, or consider some kind of stabiliser. I sometimes use PLL circuits (you can get 1 kHz steps on any band up to 30 MHz with just three cheap 74HC chips) or a fast "huff-and-puff" stabiliser for stable tuning with very small step size - see http://downloads.hanssummers.com/qexnov98.pdf - which is astonishingly stable and very cheap to build.

Howdy

I didn't describe this fully.

Dissipation protection... Put the diode of an optocoupler with a resistor in series across the pass device's emitter and collector. Then connect the opto's transistor to the reference feeding the base of the pass device. Adjust the resistor in series with the LED so that when there's too much voltage across the pass device the led lights and decreases the reference voltage which reduces the current in the pass device.

Another way to do this requires a zener, two transistors and three resistors. Optos are cheap enough and it's less parts to wire up.

I fused the output in case something breaks, to keep the circuit from being slagged. In a short the thermal breaker on the transformer took about 45 seconds to trip. I've no idea what the fault current was but the needle of the lazy ten amp full scale meter that's built into the charger was slammed forcefully against the stop.

Thanks Grumpy. I'll check supply voltage next. It's not a thermal
problem. The output is nice and stable until key down when it pulls.
It's also frequency stable during keydown, just on a different
frequency. The oscillator isn't keyed, so I don't think it's an
oscillator startup issue.

Hi, Bill.
Indeed it is a great looking project.

I don't see anyone attempting to answer you question about why the
early transmitters always doubled or tripled from stage to stage. As I
recall, this was used to minimize the loading on previous stages as a
subsequent stage was tuned. The loading caused frequency changes. This
was used only on triode tubes. When screen grid stages were used, it
was no longer necessary.

Further research would have shown 160 meter crystals were frequently
used to control 80 meter transmitters. It wasn't just because the
higher frequency crystals were not available. They were just more
expensive.

Again, a great looking project. I do see a modern resister in there,
however.

=======================================
I am using a Wahl battery powered soldering iron since the 1980s
However the battery charger is rather crude ;just a transformer with an
embedded diode.
I have changed the charging circuit by using a 12V transformer
,rectifier and an LM317 and a switch enabling charging at 300 mA (when
soldering iron is in use)and 10 mA (permanently) when iron is not in use.

I'm missing something. You said that the 'driver' etc were disconnected
and the osc is not being keyed.

So what is actually being keyed?

As I recall, this was used to minimize the loading on previous stages as a subsequent stage was tuned. The loading caused frequency changes. This was used only on triode tubes. When screen grid stages were used, it was no longer necessary.
>
> Further research would have shown 160 meter crystals were frequently used to control 80 meter transmitters. It wasn't just because the higher frequency crystals were not available. They were just more expensive.

Thanks, Paul. There wasn't really a question there other than the rhetorical observation that 'straight-thru' operation on 7 Mc and above wasn't the norm. Thats not always clear to the reader in year 2008!

As for the modern resistor...umm, well, there's more than one in there at this stage of experimentation :) Will take care of that after nailing down all of the parameters.

I see I've done a poor job of writing up the problem statement.  The
VFO at ~3.050 feeds a SA612 whose internal oscillator runs at 4.0 Mhz
and mixes the two to come up with ~7.050Mhz.  Output from the mixer
goes through a tuned bandpass filter to a class A driver and then to a
class C final.  When I found I had a problem with the VFO staying on
frequency during transmit, I disconnected the driver stage and
replaced it with a resistor termination.  The problem stayed
consistent.  The SA612 and the buffer/driver stage are both keyed.

It could also be a loading/buffering issue.  If the load the VFO sees
changes when you key on the rest of the system, that will also cause
pulling.  You need lots of isolation between the two pieces.  A gain
stage with good front-to-back isolation followed by an attenuator will
provide plenty.

==========================
'Deep Cycle' batteries should be charged with a current not exceeding
0.1C , meaning that a 80Ah battery should be charged with a current not
exceeding 8 Amperes.

I've located the problem.  I thought it would be something pretty
subtle and it turned out to be just that.  One of the pins on the
SA612 did not go into the socket properly.  It bent under and was just
```

almost touching the socket contact. I guess it was capacitively
coupling to the VFO output instead of getting a good feed. I've
straightened it and I'm up and running.

Thanks for all of the suggestions.

72,
Kenn

I've located the problem.  I thought it would be something pretty
subtle and it turned out to be just that.  One of the pins on the
SA612 did not go into the socket properly.  It bent under and was just
almost touching the socket contact. I guess it was capacitively
coupling to the VFO output instead of getting a good feed. I've
straightened it and I'm up and running.

Thanks for all of the suggestions.

======================================================
If  your WiFi device is near the microwave oven , you indeed have a problem.
In my situation the oven is away (approx 7 - 8  metres) from the Wifi
system ,both router and laptop ,and I no longer had interference when
setting the WiFI System to the highest frequency (channel) with the
microwave oven freq at about 2390MHz.

  Guys!  I've been selling these Biquads for a long time now and
everyone absolutely
loves them.
  Check em out here...  http://www.biquadantenna.com
Sold 30 just this month alone, and get emails all the time from
clients
on how good their performance is.
   If it doesn't work, you get your money back! (minus shipping of
course)

Thanks for looking!
Pete

Yikes! I have never seen that. I would be concerned about leakage. Sometimes I have torn into things and found stupid stuff like paint over grounding surfaces or rust in the compartment. There is a critical ground around the probe entrance.

My microwave oven is in the far corner of the house and I run 100 watts on VHF and 600 on HF at times and never had trouble. I never tried the laptop in the kitchen for fear of spillage. The Linksys is essentially on the floor to keep people in the park next door from ripping up my bandwidth. (although sometimes I would prefer geeks hanging out there to chase the rest out) No coverage problems at all. I do have an HT that gets "some" interference when I set it on top of the oven.

You might find they used 1n4148 diodes just to be cheap. Try Germanium like 1n270.

I built one out of the Handbook back in the 70's they called the Monimatch using a circuit board stripline. It was easy to cut rather than etching. I don't remember the year.

In the 78 issue there is one as you describe. The broadband torroid sensors are about standard in the autotuners and in some radios because they tune up at low power. They are small and don't add much inductance. You might even build it into a qrp rig and use a multi function meter scrapped out of an old tape recorder or a led bar graph.

================================
High intensity LEDs (for example those as used in traffic lights ,225 ea
per light) already light-up at 45 microampere and hence can be directly
used as a reflected power indicator instead of a meter.

The laptop computer is downstairs about 10 feet from the microwave, and the
wireless router is upstairs about 30 feet away with a desktop(and the path
goes through three walls and the floor.  The microwave doesn't wipe out the
laptop, but slows things down a bit.  A directional antenna would solve the
problem.  I'm not trying to increase range at all.
```

Fixed. I was feeling guilty so I ran it through the optimizer in
4NEC2. I haven't built a 5 dipole AMOS yet using these dimensions.

Typically the RF seal on a microwave oven is resonant, and I would not
be surprised if it leaks RF at frequencies somewhat removed from the
oven operating frequency.

Cheers,
Tom

Operation of an SWR meter depends on monitoring the line current and line voltage in the proper ratio. If you simply add capacitance to increase the pickoff of voltage, you'll screw up the ratio and it won't come close to reading SWR correctly. If, on the other hand, you make a directional coupler with two identical toroid transformers, you should be able to get decent directionality as well as good flatness across the whole HF range. A coupled-line hybrid (directional coupler) has maximum response where the coupled section is 1/4 wave long (or 3/4, or other odd quarter), and the response drops off as you go to lower frequencies. Where the line is short compared with 1/4 wave, the response in volts is very nearly linear with frequency, so at 2.7MHz, your 27MHz coupler will most likely have about 1/10 the voltage response (1/100 the power response) as at 27MHz. A transformer coupler can be flat within a dB over more than a 10:1 frequency range, but it is important to use the right permeability ferrite in the design. You do not want too much inductance--imperfect coupling between primary and secondary causes a rolloff at high frequencies--higher inductance means higher leakage inductance for given coupling, and that in turn means rolloff at lower frequency.

Cheers,
Tom

Cool idea, Frank!  Should work fine at low frequencies, but beware
that the junction capacitance of high power LEDs can be pretty high so
they likely wouldn't be great at higher frequencies.  I just measured
```

some low power ones a few days ago at about 20pF, which is about 265
ohms reactance at 30MHz, not bad at all, but wouldn't be so good at
450MHz.

Cheers,
Tom

Wow, there's a name I haven't seen for a while. I must be frequenting
the wrong groups. I was just thinking about you a couple days ago.
Hi Barry!

More about what Barry wrote: in the limit as the conduction angle
goes to zero and you generate a very narrow pulse of current, the
harmonics end up all the same amplitude. That's for an impulse of
zero width. Unfortunately, given limited amplitude of the current in
that very narrow pulse, the total energy becomes small. As you widen

the pulse, you'll see that the "comb" of harmonics no longer has constant amplitude, but the amplitudes as you go up the "comb" (higher in frequency)drop, and there will be a frequency at which they go to zero, and then increase again (and go to zero again, and increase again). The magnitudes follow a sin(x)/x shape, for perfectly rectangular pulses. This becomes interesting for a the design of frequency multiplier stages: if for example you want to get x4 out of a stage you better NOT run it at a conduction angle that results in nulling of the fourth harmonic! I think I was bit by this a time or two in my youth when I didn't understand this. (I'm working on something right now where I want that comb of harmonics to be all very nearly equal amplitude up to about 100MHz, and that tells me how narrow the pulse must be.)

Cheers,
Tom

Next time you try this, put the oven in defrost mode for about 30 seconds. The "problem" should resolve itself. };^}

Your Motorola phone is 2.4 GHz model the results are interesting, but
not conclusive since the seal is probably only effective for some 10's
of dB's and your phone system has an effective path loss of perhaps 100 dB.

I put one up I use with a WiFi repeater and I can see dozens of
wirless routers in my neighborhood. The antena i mounted at about
20ft on my chimney. There are about 8 or 9 with no security. If I so
chose I would never have to pay for internet service. There is another
subdivsion behind my house I havent even looked at that one yet.
Strange thing I know 3 of the people who have the open systems and
they are farly savy about these things. I wonder if they are leaving
them open on purpose.

Jimmie

I'm a looking at my tentec 1202 swr kit I a built. They usin' dual
stacked iron toroids just large enough ID to pass an inch long  piece
of RG174 coax and 10 turns of 26 AWG enamel wire.

I would think 10mW-ish (+10dBm) leakage around the seal of an oven
would be reasonably safe, this is down from 1kW (+60dBm) output from
the magnetron.

50dB attenuation should have a marked impact on range for a cordless
phone.

Still all rather inconclusive, but maybe time to buy a leakage
detector just to be safe...

It would certainly be best to remove the interference. If you have 4 bars now, 5 bars might not do away with the problem. Moving the microwave just 5' more might be enough. You may have to bite the bullet and put in some wiring to move the router.

Some of these guys are prone to take a practical problem like yours and turn it into a full-blown engineering problem or a swap meet for their break through technology or even an opportunity to throw mud. One engineering problem we faced was how to contain UHF security and housekeeping repeaters to a high rise building and it's underground structure. The final result was 99% coverage in the building and the parking structure, but when security went off the property, the radios went away. Visits to other buildings showed no coverage there either. We had to do that for both security and so we could get co-ordinated for licensing in an urban area. But it was a multi-million dollar system. This is free.

Placing one of those in an upstairs room is an invitation to the neighbors. I run a combination of wired and wireless. Wired to the desktop and to a port replicator for the laptop and wireless to a print server with several printers in a shop area, and the AP is off unless I want to roam around or do print jobs. There are times I have printed from the laptop, wireless in the shop to baby-sit print jobs, but it keeps the office clear and quiet. One of these days I will have to run a cat5 out to the shop. It is simply faster and more secure. The end result is my router, 1 foot off the floor with the power set to 50% to do all I need to do.

Olen jopa itse h�mm�stynyt siit� peittelem�tt�m�st� ydinalan panikoinnista, jota jo parhaillaan p��llemme kaatuvat ydinekotuhot t��ll� netiss� aiheuttaa. Oli tosiaan t�ys yll�ri miten SELKE�STI ydinlobbaajat lopulta alkoivat oivaltaa ydinalan syyksi nykymaailmamme jyr��viin tuhoihin.

Mehil�istuhon massiivisuus n�ytt�� olevan kulminaatiopiste. Eli viel� viime vuona t�nne oli aika harvat kirjoittamassa, ett� ydinala tulee jatkossa tappamaan kaiki maailmamme mehil�ispopulaatiot. Toki silloin asiasta kirjoittelin. Mutta tajuavia oli prosenteissa. Nyt kun p�iv�st� toiseen k�y JUURI kuten olen esitt�nyt on jotain aniharvaa ydinpoliisia lukuunottamatta alkanut faktat upota. Jopa mehil�iskasvattajaliiton sain viimein tajuamaan, ett� ydintaposta on kyse. Aiemat ydinalan disinfot vaikenivat muutamissa p�iviss�. Hienoa, ett� reaali alkaa kinostamaan ja ly�m��n massoina l�pi viime vuona viel� totaalivaikenevaan lehdist��mme my�s. Ilmeisesti 90% mehil�iskato ja sit� seuraava 1/3 osan ruokakato alkaa n�ky� niin kiistatta. Ilmeisesti ydinhallintomme on menett�m�ss� peli� koko laajuudella luonnon tuhoamisensa tiell�. Koska TABU:ja on laajasti nyt lis��:

A/Maailmanlaajuinen ilmoitettu niin sammakkoel�inten, kuin matelijoiden kuoleminen niinik�� maailmanlaajuisesti ydinp��st�jen tritiumsadelammikkoihin on kylm�sti m��r�tty vaiettavaksi 100%! Aika h�rski aihe, kuin sent��n kansainv�lisesti todettiin faktaksi toki!

B/Maailman kaikki tunnetut havumets�t tulevat kuolemaan muutamissa l�hivuosissa. Japanista, Portugalista ja Siperiasta v��j��m�tt� 90% metsist�mme l�hivuosina tappavista millisist� m�ntyankeroisista on tehty l�yd�ksi� per�ti 40kertaa. Vain hetki en�� ja ydinteollisuuden s��hk�lle ei jatkossa ole lainkaan puuta! Tarkoin on vaiettu, ett� Ven�j�n puukauppa takkuaa sik�l�isist� megamets�tuhol�hteist� jo. Aihe on SELKE�STI 60v k�ytt�harhoilleen suunnitelluille ydinlaitoksillemme suoraa kuolemaa! Mega TABU! Ilman muuta.

C/Kaspian kampamaneetit ajoivat Merentutkimuslaitoksen meri�mme kartoittamasta h�rskimm�n p��lle ei edes kalastajia ulkomerillemme sallita raportoimaan maneetti-invaasioita. Kyseess� kun on se keskeisin kulminaatiopiste, jonka TVO:n ydinlauhdekumpuamiset tuottaa megatuhona. Raportointiin pestataan nyt silkkana sikailuna amat��rijoukkoa muka tutkimaan levi� vaan. Ydinhallintomme t�rkyilee aiheessa niin, ettei mit��n rajaa. Kampamaneettien tiedet��n jo kautta maailman tukkineeen voimaloiden massiivivesikanavistot kuin korkki pullot. Ruotsissa tilanne on jo sellainen, ett� ydinvoimaloissaan on 80% pysyv�t varotehonalenemat.
Pian -50%. Tai kuten Ven�j�ll� merilauhteesta ydinalalla on PAKKO luopua, koskei meren valtaisat jopa 7 800el�int�/m2 kokoiset tulevat kampamaneettikannat takaa en�� ikin� asiallista j��hdytett� ydinvoimaloille.
Mega-TABU
aiheena my�s.

D/ Niin t�m� mehil�iskato johtuu tunnetusti ydinionisaation aiheuttamasta ionosf��rimuutoksen suunnistusharhauttamisesta. Joka siis eksytt�� muuten terveet mehil�iset pois muutoksillaan pois tutuilta pes�ns� paluureiteilt�. T�st� tabusta alkaa asiis puhti olemaan ydinalaltamme poissa, kun KAIKKI huomaa miten kato etenee. Aiemmin tekaistut virusvalheet eiv�t uppoa kansaan. Koska jopa mehil�iskasvattajat huomaavat, ett� suunistuksen ongelma ja ydinvoimalan l�heisyys ratkaisee suoraan mehil�isten h�vikin! Siksi massoittain TVO:n l�hist�lt� pelastetaan mehil�ispesi� turvaan ydinsaasteilta It�-Suomeen. Jotkut yksinkertaiset ydinlobbarit erehtyy luulemaan n�in hetkeksi kasvaneista paikallismehil�ispopuloista, ett� kaiki ik��nkuin olisi kohdallaan, kuten enneen. Ei toki!(

E/ Ruotsissa on kaikien aikojen rajuimmat mets�palot 02.06.2008. Koko Etel�-Suomessa mets�palovaroitus. Tippaa ei vett� olla tuttuun tyyliin saatu oikeastaan sitten lumien. Kuka oikeasti yll�ttyi, ett� jo viime vuona viimein jopa EU:ssa my�nnetty -40% ydinaavikoituminen etenee varmasti tappaen yh� hurjemmin. Kuka en�� edes muistaa, miten mm. Portugali paloi kokonaan superkuivuuksiinsa. Tilanne jatkuu ja pahenee. Ranskassa my�s jo viime kes�n� mets�� kuivettui enemm�n kuin s�teilyll� pilattu ydinaavikkomaa kasvoi. T�m� vuosi on taas edellist� pahempi. Viel� koettaa toki Ilmatieteenlaitos ved�tt�� hiilidioksidilis��ntymisen synnyt�mine +30% sadantakasvuharhoineen. Pelkk� vilkaisu jo ennen varsinaista kes�� kuolevaan ja kuivettuvaan luontoomme kertoo disinfon ydinalan panikoinniksi. Virannomaistemme luotettavuus l�henee syyst� nollaa. Ydinala tappaa ja takuuvarmasti niin kauan, kunnest tuhoaa v�hint��n itsens�, kenties s�teilyp��st�ineen koko ihmiselon mahdollisuudet my�s. Ja mik� oleelista ydinalamme TARKOIN tiet�� mit� ydinkauhuja saamme jatkoon n�hd� s�teilyjen kirist�ess� el�misen mahdollisuuksia hetki hetki, hetkelt� kaikkialta ymp�rilt�mme!((((

PS. Kuten olemme huomanneet lehtien sivut yht �kki� t�yttyv�t virannomaisuhkailuista siit�, ettei nettiin saa jatkossa en�� kirjoittaa edes n�ist� mit� ymp�rill�mme tapahtuu? Tajuaako kansamme miksi? Koska ydinhallintomme tiet��, ett� jatkossa kyyti k�y niin hirve�ksi tulevine ydinp��st�jen punasadekausineen, ettei siit� saa antaa edes silminn�kij�lausuntoja en��! Tajjuatteko, homma on t�ysin poissa ydinalamme hallinnasta. Einsteinin varotukset alkavat saamaan lihaa rajusti luittensa ymp�rille. Yksi on tulevassa varma ydinala vetelee syyllisin� viimeisi��n!

If stealing internet service from the neighbors is your intended
purpose, you selected the wrong type of antenna.  A sector antenna may
be a great idea for running a WISP or central access point, where
you're never sure of the direction the client radios are coming from.
It's a bad idea for use at the client end.  The idea is to pickup as
little interference as possible.  You're reception of 9 stations is a
problem as any one of these could provide sufficient interference to
make your pirated internet connection useless.   I suggest you look
into a panel or dish antenna, which will provide a much narrower
horizontal beamwidth, with the added bonus of more antenna gain.
```

>Strange thing I know 3 of the people who have the open systems and

I was running an open access point at my office for a while. However, I was also monitoring connection attempts and traffic. I figured that nobody would bother. Wrong. I had some bum in a pickup truck and camper, connect regularly to make VoIP phone calls. I had no problem with him using the system and we eventually came to an arrangement. However, he stupidly told all his friends, who immediately abused the system, so I locked it up with a WPA password.

In another incident, one of my customers was in a hotel that wanted real money to use their Wi-Fi. (This was about 6 years ago, before the widespread proliferation of free Wi-Fi service). So, he connected to a random open access point. The security on his laptop was more than a little lacking (writable shared folders), resulting in the installation of multiple trojan horses, spam bots, etc. I suspect the open access point was an intentional trap set for hotel visitors.

That sounds like it's the problem, and those are the solutions I'd suggest -- Tim just got there first.

Do check the supply voltages to the VFO while you're at it, though -- changing VFO (and buffer stage) supply voltages will also pull the VFO frequency.

My home system is "1540 Jackson Ave" which is my address. The assumption is that someone wanting to use my system can bang on the door and ask permission. My office SSID uses the company name.

>I think that "wrong type" (referring to OMNI, apparently) of antenna is
>perfect, given there are a few access points within range.

I'll stand by my statement. Unless you're running a mesh network, an omni at the client end is a bad idea. The client knows the direction of the desired access point and should use a directional antenna to minimize interference. In my limited experience (I ran a small WISP and neighborhood LAN/WLAN for a few years) interference is the most serious impediment to reliable operation. The more you can do to NOT hear the undesired stations, the more reliable the connection.

>You can
>"bridge" multiple access points for better throughput ...

Sorta. You can do route switching easily enough, but load balancing between multiple internet connections can't be done without IP bonding, which requires everyone's cooperation (including the ISP's). The problem is that you can't use multiple ISP's to improve the download speed from a single connection. For example, if you want to download a large file, it will only go as fast as the speed of the fastest ISP connection. The other WAN interfaces remain comatose because there's no way to bond the single destination IP to two different download streams and routes. You can download something else using the 2nd WAN interface, but you can't use it to increase the speed of the first. Uploading has a similar limitation, where you can't improve the speed to a single connection. Where such routers work best is if there is a LAN full of users sharing multiple WAN connections, not for a single user looking for "better throughput..."

I've used a few of these with moderate success:
<http://www.edimax.com/en/produce_list.php?pl1_id=3&pl2_id=>
(See load balancing and multi-homing routers near bottom of page).

Incidentally, multiple cient radios, run to a passive combiner in a single omni antenna is a total loser. The FCC specifically proscribes synchronizing wi-fi radios. Even if the isolation can be increased sufficiently to prevent receiver overload, it's highly probable that a receive packet will arrive exactly when some other client radio goes into transmit. Some relief can be obtained by using different non-overlapping channels (1, 6, 11), but only with expensive bandpass cavity filters. The spread spectrum spreads quite nicely into the spectrum of the adjacent radio.

You're right on the trail. Most oscillator circuits are operating deep in class C. The exceptions are called "marginal, doesn't always start" oscillators :-).

Some oscillators make the crystal operate on an overtone. An overtone is often very very close to a harmonic. In this case the LC tank chooses the overtone where gain is going to be greater than one. Overtones close to odd harmonics are usually much more active in the crystal.

Other oscillators make the crystal operate on the fundamental, and the output picks off the harmonic. This is where the electron coupled oscillator shines.

It's possible to have the crystal operate on the overtone, and then electron-couple to pick a harmonic of the overtone. You see this in some 40's/50's/60's era VHF projects.

> But in a doubling amplifier stage am I counting on having enough
> harmonic content at the input or am I creating the harmonic with the
> non-linearity of the amplifier?

Mostly creating. It doesn't hurt if there's some harmonic content at the input. Again, for efficiency most of the power stages will be in class C already, and if they need to multiply in a non-power stage they'll set it up to make a lot of harmonics.

Individual stages are sometimes configured in push-pull to favor odd harmonics over even ones, or are biased to be favorable for the desired harmonic.

Tim.

Which raises the question, if someone uses your access point without
permission are you within your rights to do whatever you please with the
packets (and their contents) you detect?

Seems fair, steal my airwaves and I'll steal your data in return.

LMAO!  My SSID is the same as my front gate Password.  That way I never have
to worry about opening it when I get home from work and the party is always
in full swing when I get there!  It's a little bit bothersome when dead
bodies turn up in the moat though!

As far as the FCC is concerned, I suspect that the usual "third party reception" rules would apply. If the communication is transmitted over the airwaves but is not intended for you, you're permitted to intercept the communication but *not* to make gainful personal use of what you overhear.

There was one company which tried to prosecute some local "wardrivers" who had publicized the fact that the company was running an open wireless network. The FCC not only refused to pursue their complaint (pointing out that the company had created the problem and failed to mitigate it by turning on WEP), but cited the company for running an illegal Part 15 network (they were using external high-power amplifiers on their APs).

I'm reasonably sure that any criminal actions you implement with the use of such data (e.g. making any unauthorized access to a protected computer system, etc.) would *NOT* seen as legitimate by The Powers That Be, even if you gained knowledge of that data by scarfing it off of your own access point during an unauthorized use thereof.

As I understand it, there isn't any standard interpretation (even in under U.S. laws) as to what rights-of-usage apply to an open access point, in the absence of a statement by the AP's owner as to what the rules are. The FCC doesn't appear to consider this aspect of the wireless problem to be part of their jurisdiction.

I believe that in some areas, using such an AP without having received some explicit form of permission is considered to be a tort (a civil wrong) and the owner could file suit against you. Using the AP to break into a computer network (e.g. accessing files, etc.) could easily qualify as a prosecutable "computer crime".

I've read that some municipalities have passed a rule which says that the act of setting up an insecure access point, and broadcasting beacons "to the wind", counts as something akin to an open invitation... enough so that the use of the AP without explicit permission isn't considered a crime, or (I think) even a tort. This might especially be true in the case of those APs/routers which come with a WEP password pre-installed (the 2Wire models are one example) and in which the owner must explicitly disable the security feature if s/he decides that this is appropriate.

```

I remember the Wahl 'iso tip' battery irons. Nice portable tool for
field repairs (but useless for field day PL-259 assembly!). Only
problems were battery and tip replacement. The tips would eventually
fall apart as the ceramic insulation surrounding the heating element
cracked.

As for field day, once I figured out how to quickly assemble PL259's
onto RG8U, I got drafted by the radio club to handle this duty at field
day. (Strip back about 4" of outer insulation, tin the braid with a HOT
soldering gun (I used the BIG Weller gun), file down the excess solder,
cut down the braid with a tubing cuter or a razer saw, remove the center
insulation, cut the center conductor to size and tin it, then slip the
coupling ring over the coax and screw on the connector, then solder it
home (with the BIG Weller gun again!). Took about 4 minutes per connector.

Nope. Two wrongs don't make a right. You'll also find that "an eye
for an eye" and retailiation are not actionable in the USA legal
system. Simply having your rights violated, does not magically make
it open season on the perpetrator. The courts are expected to deal
out the necessary justice, not you. For example, catching a burglar
in the act does not give you the right to pound him into the ground.
You can and probably will be charged with battery for doing that.

I have some experience and opinions with Wi-Fi related crimes and
enforcement, but I don't wanna start yet another political discussion.

Howdy,

I kept the iso-tip iron in my briefcase. It heats fast and I don't regret having bought it. When the batteries went bad I no longer had a use for it. So it ended up somewhere... can't remember where. The ceramic fell out of the tips on me too. I think the engineers at Wahl should have talked to someone at Cotronics.

I got tired of tightening the tips on the guns and bought an 80W "pencil." A studly iron, suitable for soldering sheets of copper and bus bars. For me the next step up from this is a torch. It's only 80W so at first blush I expected a higher wattage gun to work better but there's a lot more thermal mass in the iron. The copper tip is a slug about 1/2" dia and 1-1/4" lg. It makes fast work of PL259's.

I like the tubing cutter technique if the coax has enough braid. Some of the junky stuff I just flood the connector with solder through the connector's holes and mostly it works. I've tried wrapping the scant braid with fine wire first which may help. Buying or scrounging good quality coax with decent braid coverage is the best answer.

I thought the crimper for PL259's (on RG8 size coax) was a great idea but after reading some reviews and looking at the photos of cracks in the connector I'm not so sure. I thought of buying a set of dies and fixing them to a hefty arbor press I have in the garage. Though soldering has proved reliable and I like reliable.

73,
Grumpy

In looking closely at his photos, it appears his circuit is based on the Analog Devices SSM2166 (product data: http://tinyurl.com/6eadpn). The specifications indicate it *can* be operated cleanly. Of course, to set it up requires at least an oscilloscope... which many hams don't own (or know how to use).

Based on the photos I've seen, I wouldn't buy one because of the poor soldering:
http://img105.imagevenue.com/img.php?image=97441_VoiceMax_122_173lo.jpg.
I'll just continue to use my 2-tube (2x 3-500Z) speech "processor":

I dont steal internet service but I do have an arrangement with a
couple of my neighbors so we can use each other service.
This has come in handy a couple of time now in just the last few
months when my cable went out and another neighbors cable modem went
out.
Its also a ton of fun just to build the antennas and be able to do it.

I must confess I have tapped in to a few unsecure home APs to check my email while traveling. These are often easier to find than a hotspot.

Jimmie

==================================
Perhaps it is useful to mention PL259 connectors with a braid fixing
arrangement identical to the one of an N-connector .
That leaves the tech to only solder the centre pin.
They are more expensive (abt US$4.50 ea) but imho it's worth the
expenditure.

.

Higher gain omni has flatter /narrower beam. So it has to be pointed
more accurately, tilting as needed to connect with desired AP.

As Jeff says, there's no reason to use an omni for a client. Get a
much cheaper directional antenna and you will get more gain with less
interference. Pointing will be easier too.

Take a look at the pattern for this one:
http://pnt.zoovy.com/product/MD24-12/12dBi_24GHz_Mini_Directional_Antenna.h=
tml

Or consider a combination weatherproof box with built in panel antenna
like this: http://tinyurl.com/5kfd42
(Choose the version that has the pigtail you need)

That's the first thing you want to determine, by the way, how much
gain is needed?   Another thread....

Steve

Funny story... I work as a contractor and was in an office in Louisiana that supposedly had an internal wi-fi setup. Signal sure did seem weak for an internal connection. All the guys there said they didn't know what happened to it. "It used to work good".

Mr. Boss, the guy who installed it originally, was in town and said "hey, whats wrong with the wifi?". Turns out the little wireless router had fallen behind some other gear and become unplugged. All during this time the office traffic had been going thru the network of a nearby residence.

That would mean that only 1 of the 400 units had failed in the field.
Is that correct ?

According the photo (http://i17.ebayimg.com/06/i/000/cb/2d/2695_1.JPG) that I found on a certain well-known auction site, all but a few solder joints had what I call "reverse fillets". The solder connections should have a concave shape but instead have a convex shape (too much solder). The few that didn't appeared to be overheated, with a grainy appearance. I hate to say so but, though you've had a low failure rate, they definitely wouldn't pass scrutiny to meet Mil, CGMP, ISO, or IPC standards.

You are right about possibly having too much solder... but that is
certainly not a reliability issue.
Grainy appearance of some joints is not uncommon for the new RoHS
(high-concentration of tin) solders.
As for passing military specs... that was never our intention with
this product. Thanks for your comments.

```

Problem is, you don't get any visual output until the 1.6V biases the LED, much higher than a germanium or silicon detector diode in a traditional bridge. Some of the high-efficiency LED's are even higher forward voltage drops, and can exhibit weird visual hysteresis effects too at low current - meaning that they turn on at some current but don't turn off until a much lower current.

Many QRP'ers use a clever idea of using an auditory output from the
bridge. For example Fig 7.46 in EMRFD. Works very well in night-time
QRP'ing, and tuning to reduce the squeal is incredibly intuitive.

There are outfits that make Omni Antennas for the 2.4 Ghz Band, that have Down-tilt designed into them. This helps deal with the flattening of the Vertical Polarization for local connections. I have one located on a 60ft Tower that has multiple AP's at various Azimuths, with ranges out to 2 miles. Works well for a Central Distribution.

LOL.

His website claims that Mouser Electronics is a "partner." Searches on Mouser for "Telstar" and "VoiceMax" return zero results. Hmm. . does buying some parts from Mouser make them a "partner." If so, I'm a "partner" with Mouser, too.

LOL

The dictionary defines partner as "One that is united or associated
with another or others in an activity or a sphere of common interest."
So yes, in your example... you would be a partner of Mouser.

They might not be selling where you live, but over here in the UK the shops can't get enough of them. The Linux ones are outselling the XP ones by a factor of 4 to 1 - partly because of the price, and partly because the performance with XP is pretty bad, especially when you add all that anti-virus nonsense.

I just got four of the 10" for £135 each (about $200). They run Xandros Linux and are excellent for most computer users - you can browse web pages, write and receive email and type documents with just the basic supplied software. Performance is amazingly quick, and you don't need to worry about viruses. There are lots of ham radio programs available free on the 'net for them...

I know I dont have a problem with Linux either but casual users here
in the
states are afraid of it. I use Linux or various versions daily at work
and love
it. They are selling for about $270 here in the states. Still a
bargain. I was in
the process of building a car PC but that project ended when I found
net-
books.

The new generationn of mini-laptops like Asus eeePC and I believe also
the similar devices from Acer and Dell run on 12 V -DC
They all use a Pentium Atom N270 processor

Frank   GM0CSZ / KN6WH

PS:I am happy with the ASUS eeePC

I can't understand the reluctance of the Americans to use Linux. There has been no real reason to use Windows for a long time (unless you want to play games, but a PS3 is best for that). Over here in Europe, Linux uptake continues rapidly - as each new Windows virus or worm hits, ever more people and businesses migrate.

The last time I entered the 'States, the Customs guy demanded to look at my laptop, and see that it would actually work and that I wasn't importing a bomb. I started it up, and got my very pretty 3D Gnome desktop up, and he asked me what it was. I then got a lecture about how it was "un-American" and "Commie" not to use Windows! The fact that I am a Brit, and that Fedora (my usual distro of choice) is American, entirely passed him by...

Hi,
I've gotten far enough along with this project to where I'm ready to toss it out for public scrutiny, so have at me, guys.

I'm a receiver guy - never built a tube transmitter from scratch and this is my first go. My goals were, in no particular order, to build something with a early 30s breadboard look, xtal control, 40/20 meters primarily - 80/30 as bonus, moderate power for getting on the air barefoot while not overpowering a future amp idea...and of course using accessible parts.

This is sort of my compilation of ideas from old QST articles. Robbed ideas from this and that to make them fit. I made some major boo-boos at first but I think I finally have them sorted out. Something that dawned on me a little bit slowly is that none of those old xmtrs were set up to operate 40 meters with a 7 Mc xtal. Much of the emphasis was on double this/double that. Nowadays we have 7 and 14 Mc fundamental xtals abounding so I went the route of reinventing the wheel so to speak.

The rig is working at this stage...at least straight thru on 40. Waiting for some other bits and bobs to carry on to other bands. The note sounds good and its nothing I'm reluctant to put on the air. On the other hand its a massive amount of wood and metal for a measly 5 or 6 watts :) A little slatboard 6V6 chirper would have been much easier.

Anyway, I'm not a veteran with old xmtrs so I'm putting it out for comments, questions, critiques, etc. Flame suit is handy!

Looks SUPER COOL! How's the harmonics? Did you use any external low pass filter? Spectrum analyzer trace available?

Keep playing with it! Looks like a neat little project!

Thanks. No I can't answer any of the harmonic issues. My closest
neighbor is still an antenna-bound tv viewer and she doesn't report any
interference...which was on my list of goals as well. It has been a
limiting factor in the past.

Beautiful! Would you consider a breadboarded arc or spark xmitter
for your next project? Some years ago I did one using the obligatory
Model T spark coil, on 80m, that lit up a 12W bulb dummy load quite
brightly.

Michael

Looks good, no, very good. Better than my home made transmitters.

On the schematic, you missed a strap on the doubler coil. The ground pin should be connected to the nearby "coil" pin. I didn't go over the schematic in detail but I was interested in how you connected the doubler coil.

Just a matter of taste of course, but I find that using dots on wire connects, even with the use of arced cross-overs, improves readability ;)

Obviously just joking with you. Comedy is often a stress releiver. Apple
is the one with the Soviet corprorate model.

Many of the laptops will operate well at 13.8 if you disable all the alerts
and auto shutdown features. You also need to remove the battery so that it
won't run it down. Some will get goofed up thinking there is a shorted
battery though. I used to run my old Panasonic on 12v direct to the battery
input terminals without incident.

I have an APC TravelPower adapter which claims to pull 10 amps at 11-16 v
input. for 3.6 amps at 18v. Ouch! A small msw 120v inverter seems to be a
lot more efficient than that.

Maybe it is because it can be very difficult, if not impossible, to find necessary hardware drivers. Especially, if you have some of the latest equipment models. I have found Linux to be more useful on older computers as one is much more likely to find the necessary drivers.

For example have recently added a new HP all-in-one laser printer that includes a scanner and FAX. I have it installed on a dual boot (Linux/Windows XP) system. While I'm able to print with the Linux system good luck trying to get the scanner and FAX working. That's just one example. I have a litany of them.

Regards,
Danny

Funnily enough, I have much the same, but found that HPLip handled printing
perfectly, and Xsane handled scanning. Hylafax also works very effectively.
No difficult installation or configuration required with the /very/ latest
hardware - modern Linux distros have all that pretty much licked!

Just don't buy Canon or Lexmark gear - both companies /actively/ /discourage/
the development of Linux drivers.

Bob

Super job, Bill!!
Who cares if it only does a couple of watts, it's beautiful!! I have a
replica 1933 TPTG transmitter that is surface mount, wood base. (built by
another ham--nice job as well).

I am almost ready to begin fabrication of a new transmitter that I have been working on for a long time now. However, one detail is still eluding me- I would like to use a single rotary switch to select taps on two different coils. In-line ganged switching would be inconvenient for my layout. Is it possible to homebrew a mechanical linkage to turn two switches? I have a front panel and metal deck (vacuum tube construction style), so I could mount gears and cams and stuff, and my layout does have a good clear space between the coils, so there is room. My problem is that I have never read anything about doing this and don't know where to begin looking for parts, etc. Again, I have two coils with four taps each for 40, 20, 15, 10m.

Thank you very much for any thoughts on this matter.

73,
Ross, NS7F

Look at the parts assortments that Robotics Hobbyists buy, from e.g. Jameco and other places. http://www.jameco.com/ search for "robotics".

Berg and Small Parts Inc sell gears and sprockets and roller chain in small quantities but they are not cheap. Jameco is cheap.

Sprockets and roller chain or belts are surprisingly effective if not all your shafts are in-line.

For low-level switching, using relays controlled by DC voltage busses is great. Surplus small relays are available in vast quantities at very cheap prices. For non-mechanical switching, diodes can be biased on and off by DC voltages to act as switches. But once you get to higher level switching (e.g. transmitter tanks) the cheap relays may not take the currents or voltages involved. Still, there was an article in QST a few months ago that used small relays to change the electrical length of a wire antenna, I was a little surprised at how do-able it looked.

I built my own 7.5VACT 21amp filament xformer. I needed to supply
-500VDC screen voltage to the center tap.So a local ham tells me the
insulation better be able to withstand at least 500VDC.

I built my own hipot tester from a voltage doubler and a bank of eight
400WVDC caps. Each cap had a 330 volt charge so like 2640VDC. I
figured no problem. I looky up the specs and see if this thingy
passes.

I googled and can find no specs for hipot testing. I came across in a
usernet group: 2500VAC at 1ma for 1 minute. That didn't really tell me
much.

My results are 0,2 micro amps thru a 1 meg series resistor at 1980VDC

source voltage. This from either the core or the primary to secondary.
The current didn't change even when I went to a 10meg series resistor.

Is there nowhere that you can get specs without paying big bucks for a
UL or IEEE book on the topic?

HI from Ken, G4KIR,

Why not just borrow (if you don't own one that is) an Electricians
insulation tester, known over here in the UK as a "MEGGER".
These units can produce around 250-1000volts (if you can get hold of a good
one).
This will test your insulation no problem.

Hope this helps, cheers, ken, G4KIR.

I'm surprised that you couldn't find UL, IEEE or MIL-SPEC (or MIL-STD) sources on the net through Google or any other search engine.
Just taking the snippet you did come across, I believe that it means that you must maintain a leakage current less than 1 ma. for 1 minute with an applied voltage of 2500VAC (about 3500V peak). This is so far above your typical operating conditions, I'm tempted to say you passed. You do mention that your results were from the primary OR core to the secondary instead of primary AND core to the secondary, which is typical for this test, but I'm not sure it matters for a home-built. I used to have to do a test like this using 1500VDC with an automatic tester. If there was a problem with insulation, it showed up quickly. If the room lights were dimmed, you could see the place where it failed by the arc to ground.

Howdy,

A good rule of thumb (derived from many UL specifications) for equipment with a safety ground is use twice the operating voltage plus 1KV AC with a test period of one minute.

For reduced test time, one second is allowed for _production_line_ testing with increased test voltage

So for equipment operating at 115VAC you'd qualifying test of 1230VAC from primary to secondary for one minute (use 1250VAC.)

Isolating components like transformers often have to meet the requirements for double insulation so they are tested at twice the basic test voltage which is where the 2500VAC test value comes from.

Often the basic test voltage 1500VAC is applied from input to ground (chassis) and the double insulation test voltage of 2500VAC is applied from input to output. Because the output is not tied to the safety ground.

The criteria for failure is non-linear rise of applied voltage or a sustained arc or measured current above some value. The current limit varies but 3mA is a good value for equipment that is safety grounded (not double insulated.)

UL also requires the hi-pot machine to be capable of 500VA output.

Double insulated transformers tested to IEC standards for the EU with it's higher nominal line voltage may be subjected to hi-pot voltages as high as 1500V primary to ground and 4000VAC primary to secondary for one minute.

Caveats

Hi-pot only a test. There are are dimensional requirements (safety from conductor spacings) and requirements for durability of insulating materials. You could still grossly violate the standards, producing a dangerous component, and pass hi-pot. Two pieces of heavy build magnet wire twisted together will usually pass 5KVAC hipot, would you trust that with your life?

A person should to follow and understand the applicable standards under fear of fire, injury or death.

And as always, all of the above may be horribly wrong.

73,
Grumpy

Sorry, no coffee yet. I should have wrote...

Often the basic test voltage 1250VAC is applied from input to
ground (chassis) and the double insulation test voltage of
2500VAC is applied from input to output. Because the output
is not tied to the safety ground.

The ones that go to hamfests and custom embroider a name/logo onto a hat.

There being no hamfests in the DC region for many months, and me having
never asked their names/locations..... I thought this might be a place
to ask.

Getting side tracked by the mention of agency requirements, I didn't answer your question.

To answer your question, there is no agency requirement for what you're trying to test. Both input and output are not covered by the low voltage directive because they're both unsafe to touch. So the only requirement is operational insulation which your test proved.

I also failed to mention that Most standards allow for DC testing at 1.414 times the AC voltage required.

On Nov 13, 9:26=EF=BF=BDam, Ross Tucker <rjtu...@gmail.com> wrote:

> I am almost ready to begin fabrication of a new transmitter that I have been working on for a long time now. However, one detail is still eluding me- I would like to use a single rotary switch to select taps on two different coils. In-line ganged switching would be inconvenient for my layout. Is it possible to homebrew a mechanical linkage to turn two switches? I have a front panel and metal deck (vacuum tube construction style), so I could mount gears and cams and stuff, and my layout does have a good clear space between the coils, so there is room. My problem is that I have never read anything about doing this and don't know where to begin looking for parts, etc. Again, I have two coils with four taps each for 40, 20, 15, 10m.

A standard way of extending rotary switches 40+ years ago (notably the Centralab types) was to use a quarter-inch rod coupled to two separate switch shafts. Centralab style had flatted shafts to index their switch wafers. A shaft extender could be used with the rounded rod. All of those hardware pieces are still available at distributors such as Jameco or Ocean State Electronics. Rotary switch pieces, per se, aren't available now.

As a suggestion of a different way, relays are good ways to 'remote' the switching. Modern automobiles use quite a few relays and small, low-power coils with high-power contacts are plentiful. Relays are common in automatic antenna tuners. Four taps selected on two coils would need two sets of SPDT to DPDT contact arrangements. See Futurlec or Digidey or Allied or Mouser for such relays. There is a fairly wide range of relay coil voltages available and each relay is less than $5 in small quantities. Usual breakdown voltage ratings are about 250 V so it is no sweat to handle 100 W transmitter power outputs.

For all-mechanical contact coupling, I might suggest 'tactile' snap-

action switches (familiar name 'Microswitch') which are plentiful
now. Mechanical
coupling could be cams or sliding bars with cam surfaces on them,
switches
in-line. Sliding bars can be made from aluminum stock found at most
do-it-
yourself home repair stores. I did something like that a dozen years
ago
using aluminum right-angle stock, making cam surfaces by cutting down
the
aluminum slightly to leave the original edge as the 'cam.' The kind
of tactile
switches depends on their contact rating and what kind of RF power you
are
handling. Most on the market today can't handle much more than around
20 W.

Good luck on your project!
73, Len AF6AY

I spent a couple of years evaluating Linux here and decided to go back to Windows. I really really wanted Linux to work, but in the end stayed with Windows (98 second edition was best). Here are some of my issues;

1. Hardware compatibility is a major problem, and gets worse the later the distro. Best distros for my hardware were Red hat 5.2 and 6.2, and I could install those distros on any and all of my hardwares (about two dozen boxes), Later distros did not have drivers for earlier CDROM drives where your only other option is boot-from-CDROM, but if your bios does not have that, then you are dead. I have had a lot of experience with installations of Linux that crash before the installation is completed. If you want Linux, start with a shop or company that will sell you all the hardware knowing that that hardware will support the OS. Yes, i spent years on the linux newsgroups reading posts of all kinds of people having all kinds of problems. The multi-boot loaders also have bugs (lilo, grub, etc.) and the books don't tell you what to do if it screws up your box. Also, its a hardware compatibility problem. I had boxes where everything worked fine. Other boxes where the install crashed, the boot manager screwed up, or something else didn't work. YMMV.

2. I like iomega zip disks (100 MB) and the books say the only way Linux can support zip disks is by re-compiling the kernel and I was not about to do that.

3. Especially the later distros: they all need more ram than Windows to work (250 mb, minimum).

4. If you are serious, you need to configure your Linux firewall and the books say if you don't do it right, you're worse off than running without a firewall. I ran Linux for over a year, but got hacked within two months.

With Zone Alarm, you just put it into Windows and you get a lot of protection for no work.

5. Unless you have a high spec box (I didn't), all of the aps run slower than Windows. This is because Linux is really multiprocess unlike Windows which is multitasking (via time slicing). This is also true for OS/2 which I also spent a lot of time with.

I bought version 8 of Ubuntu a few weeks ago. they cleaned up a lot, but after the install, I got the printer to work fine, but Ubuntu could not find my modem (yes its a _regualar_ modem and that modem worked with everything else) and I don't have any other kind of internet access here besides dialup (unless I want to get one of the satellite dish deals, adding up a ton of fees and a two year contract and the legal disclaimers say they don't guarantee anything). So, I'll give MS credit for an OS that really does install on all of my hardware, and always finds all of my peripherals.

One nice thing about Ubuntu is that you can boot up totally off the CDROM and see if it ends up with the gui and you can run the aps without problems. Boot up from the CDROM takes (on my 800 mHz box) about 5-8 minutes. Ap launch is also quite slow, but will work. It absolutely will not boot up on less than 250 mb of ram.

Microsoft has become the ultimate robber-barron with its "activation" and I bought one legal copy of XP which I will run as long as I can but if internet web browsing makes any further advances, I'll consider an Apple Mac before I give Bill Gates & Thugs any more money.

The other problem is whether Apple supplies distibution disks with their computers (in case you need to re-install the OS because of, for example, a corrupted or hacked OS install). And, if you think OS-X is immune to hacking, then just google on "hack OS-X" and get 30,000 hits. Might be resistant to MS viruses, but there is a lot of other malicious code out there that is bad for your box.

Oh, yes, shut off as many of the services as you can or when you re-boot, it may crash (particularly the earlier distros) and make your box unusable without another install from scratch (unless you know how to fix what got screwed up). You could also ruin your RH 5.2 install if you did a shutdown and forgot to unmount a CDROM drive. Happend to me three times.

Oh you can roll your own quite easily.  Go to http://www.mini-box.com
and put together a combination of case, system board, and power supply.
 You'll need to add memory and disk to it, as well.  I'm currently using
an Intel system board (D945GCLF2) which comes with a dual core Atom 330
processor soldered on.  I'm running my on 110VAC but it's quite a
capable system board and I wouldn't hesitate to try to build a 12VDC
system around it.

hey scotty:

Really nice I like the page where you are holding a shell of brew. Now that's my kind of operator.

Now that MicroLO board is really sweet it's so large there must be a duplexer on there too, Plus I think I see 5 4 lead devices somewheres on that board with rock bigger than that dime. But tell me this isn't a wideband unit it's just narrow bandwidth? Or maybe your using this for RC control?

Thank you OM my transformer will not pass the 1500VAC test but it does
ok at 1350VAC, leakage down to 0,2 nano amps after I got rid of the
stray leakage caused by my test set up, always best to zero out the
hipot tester first. Thus eliminating the stray leakage. Must have
nicked the kapton insulation for it to breakdown at 1500VAC Now I'll
have to pot the transformer in epoxy.

Thanks for the kind words...yes, the microLO is the local oscillator
board for my narrowband 10 GHz transverter. Those "U-Shaped" traces are
the filters that select the correct harmonic of the crystal oscillator
(1136 MHz in the case of the 10 GHz unit). Those 4 legged devices are
MMICs (Monolithic Microwave Integrated Circuit) such as MAR-6, MAR-1,
etc. They are simple gain blocks with 50 ohm input and output, so they
are simple to use (no impedance matching!).

The 10 GHz transverter takes a 2M (ie 144.100) signal in and puts out a
signal at 10 GHz (10368.1 MHz with 144.100 in)...it basically adds the
final LO frequency (10224.000 MHz) to the 144.xxx sinal and sends it out
to the antenna. Works opposite during receive. As can be seen on my
webpage, I also have a transverter for 902 MHz and am going to start
building units for 1296, 2304 and 3456 MHz. All use the same principle
of mixing two frequencies to arrive at a third frequency. You can look
at Downeast Microwave's site to see all the neat stuff available these
days! http://www.downeastmicrowave.com/

Howdy,

Kapton tape is great stuff. It's best to use at least two full wraps. Some standards for reenforced or double insulation require three wraps where any two can withstand the hi-pot. Even where it's not required the two full wraps minimum is generally a good practice.

The breakdown could be due to insufficient creepage distance between the windings. If you can build up the bobbin with tape at both ends to form a barrier which keeps the winding centered it will help.

Another thing to do is sleeve the wire where it leaves the winding. A tape "pad" under the lead-out where it crosses the barrier tape is another option.

Although Kapton is resistant to temperature you're not building with an insulation system where the components have been aged with each other at high temperature in oxygen to see if there's any degredation due to chemical reactions. So the temperature rise of the transformer should be limited to 65C above ambient. If it's too hot to hold your finger on for about three seconds it's too hot. I'd call it a rule of thumb but I'd use the index finger for that test.

A person should to follow the applicable standards under fear of fire, injury or death. And as always, all of the above may be horribly wrong.

73,
Grumpy

Most people would build one rather than buy one and many would even
design one based on RF processing as this would be far better for
amateur use.

You would be far better off targeting gullible CB users.

Steve H

Actually, those little voice recorder modules that Radio Shack used to
sell (don't know if they still do) was used in my homebrew 2M foxhunt
transmitter for voice ID on FM...

Ilmastointimysteerio.

Nyt kuin olin p��ssyt j�ljille siit� mekanismista joka k�tket��n
ydinvoimalan systeemeihin n�k�j��n aivan kylm�sti, aloin pohtimaan
mieless�ni useita kummallisilta tuntuneita tapauksia ydinvoimalan
starttaamisten alkuajoilta. ASEA:n ty�l�isilt� olin saanut kuulla er��n
varsin kummallisen v�itt�m�n ja turvaohjeen. Henkil� oli sit� mielt�, ett�
viimeist��n noin vuosi ydinvoimalan k�ynnistymisest� eteenp�in olisi syyt�
oman turvallisuutensa vuoksi vaihtaa muihin elossa pit�vimpiin hommiin.
Kysytt�ess� syyt� moiseen, h�n v�ltellen lis�keskusteluja oli vain
kuitannut, ett� olisi syyt� seurata alkuaineiden kulkeutumista ydinvoimalan

poistoilman piipun ns. "pyyhk�isytuloksissa"? Kyseiselt� oli tivattaessa irronnut senverran lis�tietoa, ett� nimenomaan kromista on puhe. My�hemmin olen sitten selvitellyt taustoja my�s t�st� tarkemmin. Sanotaan t�h�n aluksi tukitietona, kromi kuuluu siihen erityisen haitalliseen alkuaineryhm��n, jota pitk�aikainen s�teily eroosioi voimalaitoksen rakenteista. Kromin kemikalisaatiomyrkkyin� tunnettu on mm. pel�tty 6-arvoinen kromi. Joka on vaarallinen mm. kyvyst��n aiheuttaa sy�p��. Ja sen kulkeutumismekanismi nimenomaan ilmastointiin on l�hinn� tieto siit�, kuinka pitk�ll� voimalaitoksen "yleiss�teilytausta" on kyennyt jo vakiintumaan.

Normaalilla ty�l�isell� ei toki ole edes teoreettista mahdollisuutta saada moista selville, mutta TVO:n laboratoriossa kyll� n�it� salaisia pyyhk�isykokeita alusta asti kyll� tehtiin. En halua sen tarkemmin kertoa t�h�n henkil�iden nimi�, mutta kun t�m� etenev� kriittinen kromil�yt� aikanaan sitten mitattiin, l�hti saman tien ydinvoimalasta tilanteen tiet�neet ja siit� selvill� olevat harvat. Kuvaavaa t�ss� vaiheessa oli, ett� henkil�, joka joutui t�h�n savupiippuun hakeutumaan joutui k�ytt�m��n rajua suojavarustusta tiedon kromiatomeista tultua julki. Moninkertaista suojahaalaria ja hengityssuojaimia ja vastaavia oli siit� p�iv�st� asti pakko k�ytt��. Joten oli mit� ilmeisint�, t�m� kromin mystinen kulkeutuminen, juuri kuten ennakoitiin ei ollut mik��n jonninjoutava heitto. Vaan ydinvoimaloissa oli her�nnyt henkiin jotain salattua ja kuoletettavaa keskuuteemme. Siit� p�iv�st� l�htien ei juuri ollut halukkaita t�h�n jokavuotiseen perushuoltokeikkaan vaihtamaan piipun ns. lentovaloja. Jollain tasolla kaikki vaan tiedosti kyseess� ei ollut mik��n harhakuva vaarasta. Mutta mik� viel� t�ss� vaiheessa h�mm�stytti, oli mist� mekanismista moinen voisi johtua?

Ehk� t�h�n on sopivaa kertoa vastaavantyyppinen sen aikuinen episodi my�s laitoksen nimenomaan ilmastointiin liittyv��n tapaukseen. On todella kummeksuttava havaita ett� juuri ilmastointi on niin keskeinen tekij�. Sill� on koko laitosalueella musertava perusominaisuus. Kun liikkuu ydinvoimaloiden sis�rakennuksissa ja erityisesti tietyiss� huoneissa huomaa ��rimm�isen meluisan ja vastenmielisen, suorastaan py�rremyrskym�isen ilmanvaihdon k�yt�nn�ss� kaikkialla. Ihmetelt�vint� on siin�, ett� tuuletusta ei moisissa mitoissa mill��nlailla l�mp�- saati hapetussyist� niin massiivisena tarvita. Ihmisi� teknisiss� tiloissa ei ole kuin satunnaisesti. Samoin j��hdytett�v�n� ei usein ole kuin satunnaista tekniikkaa, mutta aina l�sn�oleva hatun p��st� repiv� ylett�m�n suuri ja meluisa ilmastointi. Niin siit� ei p��se juuri miss��n laitoksen 1500 huoneissa eroon. Sitten sen seuralaisena on er�s viel� oudompi tekij�. Kun menee laitoksen sis�osiin aamuvirkkuna, ei siell� tarvitse olla kuin reilun tunnin, niin raukeus iskee. En siis tarkoita mit��n normaalia kyll�stymist�, vaan totaalista energian katoa elimist�st�. Olen joutunut sen kymmenet kerrat raahaamaan melkein jalattomaksi k�yneit� raavaita ja hyv�kuntoisia alle 20v kes�harjoittelijoita n�ist� huoneistoista. On liki mahdotonta ymm�rt�� sit�, miten virke� elimist� voi silmiss� rojahtaa jo reilun tunnin sis�ll� niin veltoksi, ettei ty�kaveri saa juuri sanaa suustaan.

Olen t�t� useasti tuuminut ja kysellyt aiheesta my�s laitoksen ylemmilt�. Vastaus on mit��nkertomaton ja yleens� vedotaan tiloissa pidett�v�n "turvallisuussyist�" alipainefaasia ja muut l�pin�kyv��. No sanomatta on selv��, ett� halusimme alkuaikoina saada puhaltimia pitemm�n ty�n tehdess�mme seisokkihuolloissa pois. Vaan aina tylysti sanottiin, ettei mill��n k�y. Koskaan muuta ei selitelty. Kun kysyi ulko-ovien aukipit�mist� hapen saamiseksi, sama kiertelev� vastaus. Kun ei k�ynyt , niin ei k�ynyt. Ihmettely omassa mieless� vain kasvoi. Kyll� t�h�n nyt liittyi jotain aivan ymm�rryksen ylitt�v�� ja ennen kaikkea ��rimm�isen tarkoin salattua. Jotain sellaista, joka tietona on elint�rke�� saada selvitetty� itselleen. Jokin asiassa m�tti ja pahasti!

Viel� er�s varsin keskeinen muistelus. My�s laitoksen ilmastointiin kytkeytyv�. Olin laitoksella tekem�ss� rutiininomaisia vuosihuoltoja. T�ll� kertaa teht�v�kenttiini kuului k�yd� l�pi ty�kavereineni puhaltimien kunnossapitotarkastuksia ja muita perushuoltoja laitosrutiinihuoltoina. Ei siin� mit��n olihan laitteistot tuttuja ja kiva saada my�s uusia kokemuksia ja vaihtelua puuduttaviin perusrutiineihin. Puhallinkoneistot ovat luonteeltaan massiivisia miehenkorkuisia monimetrisi� s�hk�moottorik�ytt�isi� meluisia yksik�it�. Niit� huollettiin miehenment�vist� peltiluukuista. Rutinoituneesti siis aamulla kyselin ja selvittelin mist� ja milloin saisin katkaista aina kyseisen ilmanvaihtokoneen k�ytt�s�hk�t menness�mme koneiden sis��n. Silloin sain kuulla lauseen jota en koskaan unohda. Aina, ihan aina oli painotettu, ett� ehdottomasti joka tilanteessa kun laitteita huolletaan on kaikki s�hk�t katkaistava. T�t� p�iv�� ennen turva-ajattelu oli t�ss� t�ysin ehdoton. S�hk�t katkotaan ennen huoltoa pois. Nyt kuin salama kirkkaalta taivaalta oli tullut laitosp��llik�ilt� ehdoton vaatimus. Koneet huolletaan ehdottomasti k�yvin�!

Siin� vaiheessa luonnollisesti kielt�ydyin moisesta hengenvaaraan asettumisesta, niin itseni, kuin ty�kaverieni osalta. Koska en t�ss� vaiheessa saanut selke�� vastausta h�milleen menneelt� ty�njohtajaltani edes tivattaessa, sanoin soittavani aina valvomoon sammuttaessani kyseisen puhallinkoneiston. Saavuimme ty�paikalle ja soitin, juuri kuten olin ilmoittanut aina katkaistessani kyseisen laitteiston. Hetken aikaa kaikki meni rutiinisti ja hommat tulivat tehty�. Mutta siin� vaiheessa, kun aloimme k�yd� l�pi nimenomaan valvomon puhallinlaitteistoja alkoi kuulutuksesta kaikua vaatimus ilmoittaa toistamiseen tehdyst� irtikytkenn�st� varsin k�skev�sti. Ilmoitettuani toimenpiteen koordinaatistot ja syyn siihen vaadittiin ilmastointikojeistojen v�lit�nt� takaisinkytkemist�. Kummastelin jo t�ss� vaiheessa miten on mahdollista, ett� useiden rinnakkain samaan ilmastointikanavaan puhaltavien flektien yksitt�ispys�ytys ei muka olisi mahdollista? Nimitt�in aina oli my�s TVO:n kursseissa korostettu miten jo yksi ainokainen rinnakkaislaite takaisi jopa kriisin sattuessa turvallisen prosessin etenemisen. Aina juuri t�h�n asti oli korostettu, ettei yhden, kahden, tai per�ti kolmen rinnakkaislaitteen poistumisella k�yt�st� olisi mit��n vaaraa turvallisuuden kannalta. Saati muun prosessinhallinnan vaikeutumisen osalta. Ja nyt yht�kki� sanottiin jo yhden koneiston hetkellisen huoltoseisokki aiheuttaa turvavaaran! Olin �llik�ll�, huomasin my�s viimeist��n t�ss� vaiheessa miten totuus ja koulutusmateriaali oli irti toisistaan. Tottakai j�timme huoltoseisokkikierroksemme tekem�tt� ja palasimme perin kummalisin tunnoin majapaikkaamme. Eteemme oli kuin v�l�yksenuomaisesti kohonnut jotain ennenn�kem�tt�m�n uhkaavaa ydinalaan liittyv��.

Kyselin vaisulta ty�njohtajalta asiaan liittyvi� taustoja ja per�ti merkillisi� juonik��nteit�. Mit��n selke�� raportointia en itse asiassa koskaan saanut. Tiedustelin ponnekkaasti my�s sit� miten edes teoriassa voidaan vaatia henkil�kunnan suorittavan moisen kamikazehuollon. Eik� edes ty�turvavaltuutetulla, tai p��luottamusmiehell� ollut mit��n sanottavaa? Ainoa vaikutus tilanteelle oli kun sain siirron sellaiselle ty�paikalle jossa en joutunut vastaavaan rupeamaan. My�hemmin kyselin miten ylip��t��n kukaan voi huoltaa hengenvaarallisesti ilmastointilaitteet, niin vastattiin vaan yliolkaisesti ettei ole minun murheeni. Sen verran sain j�lkik�teen kuulla, ett� koneet siit� lukien tosiaan huollettiin henke� pid�tellen ja k�yvin�! Uteliaisuuteni her�si ja p��tin selvitt�� mist� moinen hysteria ja suunnaton pelko ilmastoinnin kohdalla perimm�lt��n kertoi. Sain, kuin sainkin selvyyden laitostoimittaja ASEA:n osaajilta, ett� kyseess� oli varsin tarkoin varjellun ydinlaitossalaisuuden tietoinen pimitt�minen henkil�kunnalta. Jos tieto vuotaisi julkisuuteen, sen esitt�j�� kohtaisi irtisanomiset ja vastaavat sanktiot! Mist� oli perimm�lt��n kyse? Ydinvoimaloiden ilmastointiin liittyy mekanismi, joka vaatii tauotonta ilmanvaihtoa kaikissa niiss� tiloissa, joissa edes v�h�n on s�teilyenergiaa. Eli turbiinisalit ja reaktorihallit, asiassa kaikki "tekniset tilat" henkil�st�konttoritiloja ja valvomoa lukuun ottamatta pit�� olla tauottoman ilmahuuhtelun piiriss�. Sain kuulla miten pahimmillaan jo noin 15 min ilmastointikatkos saattaa kyseiset tilat radioaktiivisiksi ja niin kova s�teily niiss� silloin jo on, ett� syntyy hengenvaaraa. Jos esimerkiksi n�ist� teknisist� tiloista ilma virtaa v��rinp�in valvomoon, niin henkil�st� on v�litt�m�ss� kuolemanvaarassa!

En mill��n saattanut ymm�rt�� mekanismia, jossa ei s�teilydosimetri edes n�ytt� mit��n muuttaa noin nopeasti ilman niin vaaralliseksi, ett� hengenl�ht� konkreettisesti on mahdollista. T�m� oli joko t�rke� vale, tai sitten joku ei ymm�rt�nyt, mit� puhui. Mutta koska tilanteessa sain ty�paikanvaihdoksen selityksitt� osakseni ja kun huomioin laitosp��llik�n ylireagoinnin huomasin osuneeni johonkin t�ysin siihenastisen ydink�sityskyvyn ylitt�neeseen totuuden sis�lt�v��n miinakentt��n. Siit� p�iv�st� asti olen suoraan sitoutunut selvitt�m��n t�t�, ehk� koko nykyfysiikan tarkemmin varjeltua salausvyyhti�. T�ytyy sanoa jos olisin alusta asti tiet�nyt sen kaikki seurannaiset ja juonenk��nteet, niin ehken olisi koskaan ryhtynyt selvitysty�h�n. Ty�h�n, jonka seurauksena t�m� edess� oleva ��rimm�isen salatun ydinsalaisuuden Bandoran lippaan aukaisu sitten vaikeuksien j�lkeen onnistui! On suorastaan uskomatonta, miten juuri t�st� tapauksesta sai alkuunsa se mekanismi, joka toi p�iv�nvaloon v�hitt��n 60v ajan ��rimm�isen tarkoin varjellun salaisuuden. Jonka varjelemiseksi on perustettu mm. IAEA:n kaltaisia ydintiedon levityksen est�vi� maailmankattavia organisaatioita, mutta eip�s t�ss� vaiheessa paljasteta enemp��. Seuratkaamme eteenp�in, miten kaikki mysteerist� porras kerrallaan alkoi raottua. Haluan lis�t� t�h�n, sain my�hemmin kuulla, ett� minut nimenomaan haluttiin t�h�n ratkomaan jo pitk��n hiert�nytt� ty�turvallisuusdilemmaa. Ja sain kuulla, miten varsin selke�sti p��navaukseni j�lkeen koko ilmanvaihtoflektien huoltorutiini muutettiin sellaiseksi, ett� laitteita alettiinkin vain kuulustelemaan laakerien kunnon varmistukseksi. Vain pys�htyneet laitekokonaisuudet tehd��n virrattomaksi korjaamisensa ajaksi. Eli olin tehnyt teht�v�ni ja sain kontolleni entist� vaativampia ty�vastuukentti�.

The UC3906 is temp compensated unlike zeners which go up with temp rise and down with temp decrease. Believe me 1/10 of a volt change will fawk up the charge rate. Been there done that.

I've quick charged deep cycle marine batteries at work when I forgot to put my battery on charge on my electric bike. 55 amp in one hour no problem. Now I was using this my electric bike every day to gits to work. I got 2 years out of that deep cycle marine battery before my brushes on my motor were no longer available from Grainger. I didn't count the times I quick charged the battery at 55 amp rate but it was quite a few.

If this isn't any everyday thing make it simple, no frilles But a automotive in car charging system is the worst thing anybody to do to a battery. I'd let my battery sit on cold concrete before I'd charge it with an automotive charging system in a car.

Ahah! The SA612's input impedance will change by a lot when it is
keyed up vs keyed down.

Two ways to get around this:

1. Additional buffering between the VFO and SA612

2. Swamp the impedance change from power up to power down by adding
some parallel resistance. Should be DC-isolated from the SA612's input
because otherwise you will upset the balance.

Solution #1 requires some additional parts and current drain. I really
like the two-transistor W7EL buffer.

Solution #2 is just a capacitor and a resistor, but also assumes that
the VFO has enough drive that it won't object to being swamped.

Howdy,

There are a of couple newer devices that you might like
even more than the UC3906. Check out the UC3909
and BQ2031.

All zeners are not created equal! The 1N825 is a common temperature compensated diode and it's uncommonly good. Transfer standards built in the 1960's and 70's often used zeners... and they were good enough by golly. The venerated Fluke 335D used an ion implanted or burried zener diode and it's still one of the most stable units available.

Here's the deal, the battery voltage varies with temperature. About minus 3 to minus 5 milivolts per degree C. Not very stable! (However for temperatures between 5C to 35C it can be safely ignored.)

Now if the circuit is exposed to the same ambient temperature as the battery and your reference drifts about the same amount and in the same direction as the battery, it can be only a good thing.

A true zener has a negative temperature coefficient.
An avalanche diode has a positive temperature coefficient.
The cross over point between the two effects is around 5.6V
A common silicon rectifier diode has a negative 2 milivolts per degree C coefficient.

It's not difficult to select a couple of parts that when combined in series will produce the minus 5 milivolts per degree C desired. A 6.8V zener in series with three 1N4001 running 1 milliamp of bias current is in the ball park.

Honest to god temperature compensated charging requires a temperature sensor in the battery (thermistor usually) but it's only needed where you're charging at a rate that heats the battery or when charging over a very wide range of ambient.

The above is just my opinion and all that jazz...

73,
Grumpy

This Finnish message belongs in Newsgroups about nuclear power, not in an amateur radio Newsgroup about home construction of radio equipment.

T�m� Suomen viesti kuuluu Uutisryhm�t noin ydinvoimaa, ei amat��ri radio Newsgroup noin kodin rakentamiseen radio.

Are you sure its the VFO and not the SA612?

Jimmie

Wow, that brings back memories.  That is a receiver which came into
being right around when I did (1950's).

The tubes in it alone worth something (can be hard to get replacements
these days, just price them!)

I sat before one of those for untold hours in my younger days ... shame
SW is so empty these days ... :-(  It was an EXCELLENT RECEIVER ...

Regards,
JS

A very common modification, especially by the Navy, was to add a jack
there to monitor the diode load voltage, this makes their regular
maintenance much much easier. NAVSHIPS-0967-063-2140 documents this.

Isn't there a Diode Load terminal on the back already?

BTW: That paint job looks awful. Too shiny. I had 2 of those beasts
and liked a slightly worn look a lot better.

  They aren't that difficult to tweak to superior performance. I
wouldn't spend more than $500 for one with a good RF deck.

The NAVSHIPS document states that a Dymo label should be affixed by the jack.

Related to your other comment, I think that the one on the E-place has
been repainted.

My yellow striper came with the decades-old Dymo stickers still
attached. I swear the glues in modern Dymo labels aren't as good.

Tim.

Eilen 27.04-08 haastatteli YLE Egybtin hallitusvirkamiest�.H�n kertoi
h�mm�styneen�, ettei maailmassa ole koskaan n�hty niin massiivista
```

monikymmenmiljoonaista kansanliikett� maansa historiassa , kun nyt liikkeelle l�hteneet "leip�kapinoinnit maassaan.!" Suorastaan musertavan hiljaa on tiedotusv�lineemme olleet siit�, ett� t�llaista on tapahtunut ja n�in laajasti jo pitk��n. Egybtin t�rkein ruoka kun ei ole puhuttu riisi vaan nimenomaan maailman yleisin ruoka leip�, eli USA:n VEHN�! Samalla viitattiin, ett� Afriikkaa runnoo jo massivoituva yleinen ruokapula kautta linjan.

Samalla tutkailtiin tilannetta my�s esim V�li-Ameriikan osalta, jossa useamman maan johtajien toimesta on pidetty hiljaisuudessa n�lk�palaveereja jo pitk��n. Eli tosiaan kyse ei n�iss� n�l�nh�t�tilanteissa ole mist��n pelk�st� riisist�. Vaan nyt loppuvat ydinaavikoitumisen jaloissa niin vehn�t, lihat,maidot, juustot, riisit kuin mitk� tahansa maailman hiipuvat rehuma�ssit t�ss� ja nyt! Ydinaavikoitumisen jaloista poistui niinik�� tosiaan kalat, ja jopa hunajat. Ja ennenkaikkea my�s mehil�isp�lytteisest� ruuan tuotannostamme k�yt�nn�ss� kerralla kaikki!

Niin hurjaksi homma n�ytt�� menev�n jo t�st� tulevasta superkuivasta kes�st�, ett� t�ytyy my�t�ill� Egybtin valtiovirannomaisia. "Niin paha ruokatilanne, ettei vastaavaa olla ikin� n�hty!".. ..Jaa t�m�n kes�n sato? No sanotaan, ett� siihen verrrattuna sent��n viime vuona tuli mehil�isp�lyteruuat ja meriss� oli kaloja. Nyt on edess� tosiaan maailmanhistoriallinen hetki kun TVO:n ydinkampamaneettikasvatus vei kalat ja jopa Japanin ja USA:n ydinlauhdemeret puskee jo enemm�n meduusoja, kuin paikoin vett�. Ja t�m� mehil�iskato.. .hui kauheaa. TODELLA alkaa maalaisille l�ytym��n k�ytt�� ja ruoantuotantomy�t��!! Eli vaikkei t�st� tule selvi�m��n ydinala, sen paremmin kuin siihen loppuunsa asti sitoutuneet kansat. niin jotain hyv��. Tilaa tulee kohta hurjasti ja olen veikannut, ett� CCCP mallin mukaan vuoteen 2018 menness� alkaa ydinala olemaan sellaisessa kansanmassojen paineistuksissa, ett� vet�� vertoja tuleviin ruokar�hin�ihin. Jahka tosiaan ydinalan syyllisyys alkaa laajasti hahmottumaan tulevissa "punaisen sateitten" aikakausissamme.

Mik� ihmen punaiset sateet? No s�teilyionisaatio synnytt�� globaalin s��rintamamuutoksen vesist�mekaniikkoihin joka on kovin tuttua s�teilyionisaatioilmi�iden ry�st�ytyess� nykytyyli� mennakoivasti oikein reippaasti. Min� en miss��n tapauksessa ole mik��n "ennustelija" vaan kylm�n viile� aasianosaava fyysikko! Mm. t�m�n punaisen sateen perusfysiikkaan voi osaava tutustua mm. Hiroshiman ja Nagasagin vapaammassa historiikissa, vaikka IAEA/syyllinen USA toki kaiken kiist�� yh�.

I hacked together a 10amp contant current source, actually it tuned
out to be a little les than 9 amps and hooked it up between one of my
100ahr batteries and my shop type battery charger. So far it behaves
as expected. I just hope it does the job as expected.

Looking for outdoor omni "whip" antenna for 2.4 GHz.

Is there any reason to not go for the greatest gain antenna, given that cost is not too important (within reason)?

There are scads of these on the 'net. I'm looking for someone who has experience with one or more of them and can make a recommendation for one.

Thanks,
--

Hi, not actually 2.4 Gig WiFi but cellular wireless modem card.  I
bought one of the small verticals with a magnet mount and cabling for
about $15 ppd as I recall.  My situation is that my house is built with
```

concrete/rebar construction, metal 'persiana' windows and screens and its hard to get a signal out of here even on the various cellular bands. I think the highest band there is 1.8 GHz.

I didn't go for gain since the path to the site is only about 1.3 miles away so I opted for the little guy, about 7 inches tall, that just sits on the roof. On the other hand, a friend in a different location got himself into all sorts of problems with reflections and multiple tower sites and is now looking for a directional antenna to minimize the clutter.

Another consideration is the vertical angle between you and the site. The "high gain" verticals (I've seen ones claiming 14db) have a rather flattened omni pattern so that if you have to look upwards to your intended site you might find the gain to be considerably less, if any.

GL,
Bill

Whip antenna? What is this, for a vehicle? For a stationary location it seems like it'd be an extremely bad idea to use an antenna that 'whipped' around.

> Is there any reason to not go for the greatest gain antenna, given that
> cost
> is not too important (within reason)?

Alligator effect. Wide mouth receiving everything. If you don't need to pickup everything then why bother? It just makes it harder for your WiFi router to cut through all the noise of distant stations it doesn't communicate with. Get the right antenna suited for your installation, no more, no less.

Which leads to the constant request, when you ask a question POST WHAT GEAR YOU'RE USING.

In your case it would also help to define what sort of connection you're trying to make. Point to point, metropolitan, etc.

Since you have included the HAM radio newsgroups as your first choices,
with the Internet Wireless as your last choice,

then - as was mentioned above - what are you trying to accomplish
with this 2.4Ghz outdoor antenna ??

Since you used the term "whip" it tends to imply some physical motion or
vehicle,
vs a "vertical" which implies a stationary location.
And both imply a omni pattern - like a general Access Point -

===================================
Yes these cans work well ; the problem is the type and length  of coax .
A suitable arangement is a WiFi router near the antenna (if necessary in
a wx proof box ) with an ethernet cat5 cable running to the equipment.

Another possibility is a USB WiFi adaptor in the focal point of a
satellite dish with a USB to ethernet converter.

I recently built a Franklin antenna for 2.4Ghz.
I highly reccommend it. Google WiFi and franklin antenna.

Yes indeed the 3909 is a switch mode version of the 3906 and the
BQ2031 is a pulsed version. The 3906 uses a constant current source
and I used 10 amp and mine turned out to be like 9 amps in real life,
I forgot how many feet of 14AWG wire I used for the 10 map sense. Some
say pulsed or pwm is the way to go. Maximizing the PWM to fast charge
a battery would be advantageous. I think that's what they are using in
the hybrid cars.

This is a really dumb question but it dawned on me that I did not know
the correct answer.

In terms of old transmitters from the 20s/30s...In a crystal oscillator
I understand the concept of setting the oscillator output tank to
favor the harmonic from the crystal. (Stop me if I'm wrong already...)

But in a doubling amplifier stage am I counting on having enough
harmonic content at the input or am I creating the harmonic with the
non-linearity of the amplifier?

TIA

Hi Bill.

Remember that single ended frequency multiplier stages are usually operated in Class-C where the nonlinear operation of the stage produces the harmonics. In a Class-C stage, the grid (of the tube since we are talking about vintage transmitters) is biased such that the plate current only flows in short pulses. The narrower the pulse width, the greater the harmonic generation of the stage. If you look in the old RCA Transmitting Tube Manual, there is a design procedure where the "conduction angle" of the tube is chosen for proper harmonic generation.

Frequency doubling is unique in that two Class-B stages may be used in a push-push arrangement. Here the grids are driven in push-pull while the plates are connected together in parallel. The resulting waveform will essentially be the equivalent of full-wave rectification of the input signal. Without going into Fourier series, the resultant waveform only contains even harmonics of the input signal while the fundamental driving frequency is cancelled out.

Fortunately I was already a ham operator when my high school math class taught Fourier series *. I immediately saw the practical value of this mathematical concept and it made good sense to me. Your question is a good one and reading some of the tutorials on Fourier series (do a Google search) will be very useful to your understanding of harmonic generation and intermodulation distortion. I hope that my simple explanation will start you in your own exploration.

73, Barry L. Ornitz WA4VZQ

Thanks Barry, I get it. I was becoming distracted by some of the old
1930s articles touting the tritet osc for its ability to create more
harmonic output (true) for directly driving following stages.

I suppose thats just another way of reaching the same goal.

(btw, haven't heard from you in years - I recall your great input over
on r.a.r. +p. No, it hasn't changed)

OK, time to clarify...

Wifi (2.4 GHz). outdoor omni vertical (not whip), permanent mount on pole, to
be connected (very short pigtail) to pole-mounted wifi router in client mode.
Max output: 250 mW.

Is it true that the higher the gain the flatter the "donut" shape of the
sensitivity field?

(And yes, my terminology is rudimentary... please forgive.)

Thanks,

--

why omni on a pole in "client mode" ?

If you are attemtping to connect to a specific Access Point,
this has been discussed here zillions of times,
and there are other questions, clarifications, and solutions available -
other than an omni -
Where are you in relation to the Access Point, how far, line of sight, etc

This requires a little different "thinking" than just putting up a bigger stick
to talk to a 2m, 220, or 450 repeater -

I'm the one who initially committed than terminological crime so forgive
ME! Where is that big omni gain going to come from if not from the
vertical beamwidth? Start with the isotropic model pictured as a
spherical balloon. Squeeze it however you want to. Nothing about an
antenna can add volume to the model, its just a matter of how you
squeeze it.

In an overtone oscillator, the resonator actually forces the crystal
to mechanically resonate at 1/3, 1/5, 1/7, 1/9 etc. of the crystal
width. Due to the end effects, the frequency is *not* _exactly_ 3, 5,
7, 9 etc. times the fundamental frequency, but quite close. In
principle, the oscillator is producing a single frequency, the
(harmonic) mechanical resonance frequency of the crystal.

>But in a doubling amplifier stage am I counting on having enough
>harmonic content at the input or am I creating the harmonic with the
>non-linearity of the amplifier?

The non-linearity of the stage will produce the harmonics, which are
exact integer multipliers of the input frequency. Symmetrically
clipping stages generate strong odd harmonics, while asymmetric
stages create strong even harmonics. The following stages need to
filter out the desired harmonics.

So if you need exactly 30.000... MHz, you either have to use a
10.000... MHz fundamental crystal oscillator followed by a tripler
(and filtering stage) or order an _overtone_ crystal for exactly
30.000... MHz.

Running a nominally 10.000... MHz fundamental mode crystal in an overtone oscillator tuned at 30 MHz will not produce exactly 30.000... MHz but something quite closely, due to the end effect.

That is the only way to get actual gain from a (horizontally) omnidirectional antenna (excluding any MIMO designs).

Flattening the vertical radiation pastern may have severe drawbacks especially if the mast is swinging in the wind or some weak (e.g.

indoors) users are close to the base of the mast.

No... they gave it to him because it didn't cost much and was defective. At
my current place of employ, we have many Weller EC-series soldering stations
and over the 6 years I've been there, I've seen only a couple of failures.
In 30+ years in radio/electronics, I haven't seen many failures of these
units. I recently bought a new WES50 for myself and am very satisfied.
Tips are widely available and inexpensive.

Also look up AMOS antenna. They are easy to make and work well

I've got a cheapo CB swr meter which I thought might be suitable for some HF QRP work. Problem is that it is very insensitive on the HF freqs. Can't even get more than about 20% of the scale with 5 watts on 40 meters.

It uses a stripline for pickup and I'm wondering if maybe I should replace that with a broadband toroid configuration. Any specific recommendations? How about adding some gimmick capacitance across the stripline to increase coupling?

TIA,
Bill WX4A

I would take a look at some DIY projects for SWR meters and see if I
could use the box and meter.
I had the same problem with a meter I bought at a yard sell. I liked
it because it had a big 5" meter and a fairly decent built in 50 watt
dummy load.
Price was right too $1. I rebuilt it per plans in an ARRL pub. This
one had a stripline pickup and there was enough room in the box to
double the length, that was my first consideration, but I ended up
using a toroid transformer instead..

I have need of a directional antenna for a 30 foot path within the house.
(the microwave oven wipes out the signal).

Do you have any better details on construction?

> In terms of old transmitters from the 20s/30s...In a crystal oscillator I understand the concept of setting the oscillator output tank to favor the harmonic from the crystal. (Stop me if I'm wrong already...)

I think this is correct, but the books say that tuning the output of the oscillator can "pull" the frequency of the oscillating crystal. I have sometimes seen this.

> But in a doubling amplifier stage am I counting on having enough harmonic content at the input or am I creating the harmonic with the non-linearity of the amplifier?

Despite what at least one other person responding to this said, I can rest assure you that if you run a doubler/multiplier stage even in a linear mode, AND if you tune the output of that stage to the multiple harmonic, you will definitely get output at that harmonic frequency which is stronger than the input drive voltage. In the last few years I have built many tube stages and observed the harmonic voltage output on a wideband oscilloscope. As a matter of fact if you ever get a wideband scope and look at the locked output waveform as you tune through the both the fundamental and the harmonic frequency you will be very surprised at what you will see. All of the descriptions in all of the handbooks I have read (a few) explain this from a theoretical perspective but don't bother to actually show, with photographs of actual scope traces, how this works. It would just take an extra page or two and would make people think about what they are doing.

All amplifiers have some non-linearity, the question is what effect this has on you meeting "purity" of emissions requirements. The more important question is whether you are getting the gain/drive that you want from a given stage of amplification. Reducing unwanted spurious emissions might require more tuned circuits or measurement using a receive with an S-meter and operated many wavelengths from your antenna. Most "appliance operators" just buy a commercial rig and don't worry about anything; homebrewers might not worry either if their signals go through a tuned circuit, an antenna tuner, and an antenna for a narrow frequency range.

If you really want to blow your mind, then hook an oscilloscope to the output of a mixer with two low harmonic content input sine waves to be mixed. The raw output will look like hell on a scope. The only way to see the mixed (say, difference) frequency will be to go through at least a couple of tuned circuits that are tuned for the wanted sine wave frequency.

I've done this stuff. There are a couple of other minor matters that are not quite correct in our ham handbooks, too.

I've used those cheapo CB SWR meters, too, and yes at low HF they are not so sensitive even with the sensitivity turne as high as it can go.

What is more important is the meter reading on "reflected" compared to "forward". As long as the reflected is much lower (roughly 1/4 or less) than forward, you should be OK. Most scales I've seen will have a calibration such that reflected at about half the scale as forward means an SWR of about three to one. One of my meters has this point at 2/3 of full scale. I have always felt satisfied if I can get reflected down to one tenth, or less, of forward by manipulating the antenna tuner.

If you want to be a purist, then you might also consider locating a more sensitive meter, say 20-50 microamps DC and using that. Most of those internal meters are 100-200 microamps DC. Or, make the modification you describe below.

> It uses a stripline for pickup and I'm wondering if maybe I should replace that with a broadband toroid configuration. Any specific recommendations? How about adding some gimmick capacitance across the stripline to increase coupling?

I'm not sure it is worth the work to try this, but I don't have a good recommendation or preference to emphasize.

Well, this little dilly has several wattage ranges, calibrated at 27 MHz
of course, as well as the 'adjust to full scale, flip to REV' for SWR
readings. I could not get anywhere near full scale with the setting.

I did add some additional capacitance off of the stripline and am now
within range of the thing. It took about 10pf, a gimmick wasn't enough.
  Celebrating that success I reset the lowest ranges of the wattmeter (5
and 50 watts) to read accurately at 7 MHz. I have no fantasies about
the linearity of the circuit now nor any fantasy that the other ham
bands will read anywhere even close wattage-wise but it seems just the
ticket for 40 meters.

If I get enthusiastic I might try a ferrite transformer and just see how
much flatter that might be across the bands.

73,
Bill

hey larry

I see trouble with the bypass caps on the LM317 regulator. They have opened up and now the adjust pin, which is an op amp input, isn't bypassed, letting in massive quantities of rf and overloading the op amps ability to compare the reference voltage to the adjust pin voltage.

Thanks for sending that Bryan. It is too bad for me that is not the one I
have. From the outside it looks like it, but inside it is totally
differant. There seem to be several modles that look similar on the outside
but differant inside. The one I have has a C after the 2002.

Sounds like my power supply. One of the emitter resistors on a pass
transistor opened. The transistor did not fail. I replaced the
resistors and decided to upgrade the 2n3055 to some NTE181s. Also

modified the power supply for remote sense to allow for IR losses in the power cable.

```

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

radio/personal-intro
Subject: Guide to the rec.radio Newsgroups
Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
Last Posted: 9 Nov 2001 06:18:17 GMT
Posting-Frequency: 15th of each month

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to
rec-radio-info-request@panix.com.

I have 2 older CB BASE station radios. ONE IS SSB.. and the other is AM only

And I have a 100 + watt Knight T 175 AMP. 10 mtr and 6 mtr AMP. ALL THIS

EQUIPMENT IS IN NEED OF REPAIR. THE AM unit comes on and I got sound out of it. Squelch Noise. COMES WITH NICE TURNER DESK MIC

THE SSB radio has NO power cord.. SO I could not power it. COMES with MIC.,.

THE AMP powered up.. Made some noise. SO I pulled the plug.

Pictures of all above by e-mail.

I will trade for a NON working HF transceiver.

73

Mike WB2GLW

I have a 15volt 25 amp SMPS that I would like to convert to a +/- 15 volt power supply. I was wonder if I could do this by adding two diodes to the present two diode full wave rectifier circuit to turn it into a bridge. Also the power supply seems to be operating at about 25Khz, but the diodes are standard recovery. Would there be any benifit to switching to fast recovery diodes.

Jimmie

Hi Jimme,

Yes you can, you'll need to add a second output filter too of course. I'd make the second filter for the negative output a duplicate of the existing filter except for the polarity of the capacitors. A coupled inductor would be better but might effect the control loop compensation.

For a 15V output I'd most likely use schottky diodes for their low forward voltage and no reverse recovery (at the expense of higher capacitance.) Maybe have to add a small series RC snubber across the schottkys if there's a lot of ringing.

Any benefit to using faster recovery diodes would depend on how fast the diodes now in use are switching. I've seen crappy old 1N4004 diodes with 35nS recovery times when operating at several amperes of forward current. That's ultra-fast! But they're specified as standard recovery... this really screwed up a base drive clamp where they were expected to be slow.

If they are 1uS parts, changing to something faster should reduce switching losses. Might make the supply quieter... or more noisey! Ultra-fast parts with soft recovery would be my second choice after schottkys. They tend to produce the least EMI and what noise they do produce is easier to snub and filter in addition to low switching losses.

I forgot to mention that I made the assumption it's a forward converter that produces symmetrical output. I'm expecting it's a half-bridge converter. Other topologies would require an additional winding to the transformer.

Ralph-

Take a look at
<http://bama.edebris.com/manuals/weller/>
where the EC2002 and EC2002m are listed.  Perhaps one of these will be
closer to yours.

Right, to pick up the negative supply you has to have a waveform that
has enough negative going cycle you might be able to pick up sum
ringing waveform and rectify it. Don't expect to gits -15 volts @ 25
amps.

If you're lucky you have a push pull front end. But I don't think
your -15 is going to be regulated.

Howdy,

It's a pretty safe bet that it's a topology which will work, because the existing output is described as a center tapped full wave configuration. (If I read Jimmie's post correctly.)

I'm expecting it's a half-bridge with its 375W output. Then two center tapped full wave outputs of opposite polarity from one winding can be built.

In this case the output voltage is mainly determined by the bulk supply's voltage, the switch's duty cycle and the transformer's turns ratio. All of those are identical for each output, because they use the same secondary winding.

With a somewhat balanced load and identical output circuits, cross regulation (regulating only the +15) should work ok.
A coupled inductor would further improve the regulation.
Then sensing across the outputs (30V) or summing them might be desirable. It all depends on what the load requirements will be. .

In that power range another popular topology is the single or two switch forward converter. In these the switches drive the core in one direction then let it reset by various mechanisms.

It's kind of interesting, replace two diagonally opposed switches in a full bridge with rectifiers and you have a two switch forward converter. Then the output voltage waveform is asymmetrical and you're forced to use half wave rectification.

It's very rare to see a flyback converter at this power level with such a low output voltage. It's possible some special applications might require one but it's generally ugly and not economical.

Anyway... I think it's worth a try but I could be wrong.

73,
Grumpy

Well it works but it wasnt as easy as I thought it would be. Putting in the bridge was the easy part. I still had to find a place for another filter cap and a choke. The caps werent too much of a problem. I removed the origonal one and was able to fit 2new smaller ones in their place. Since I was going to drawing a lot less current than the PS was designed I figured I could use smaller caps. I still havent settled on where to place the choke. Its just hanging out the side for now. I will eventually try some fast recovery diodes but since the power supply origonally use stardard recovery diodes that is what I will use for now. The heat sink the diodes are mounted on get fairly warm, maybe fast ones will help this.

Jimmie

Hi,
Can somebody walk me thru the calculation of an LC circuit where the capacitor is tapped down on the coil? I see this often done for bandspreading purposes.

Tnx,
Bill WX4A

Howdy,

I'm guessing that it can be solved like this...
Consider the autotransformer action of the tapped inductor.
Then divide the tap capacitor (C2) value by the square of the

turns ratio (N) before adding it to the primary capacitance
of the parallel tuned circuit (C1.)

F=2Pi*sqrt(L(C1+C2/N^2))

I found a rigorous solution in chapter 8 of Alternating
Current Circuits by K.Y. Tang but it's too messy to type.

Thanks Grump...gonna save that for my files but I think I need to
clarify my question. One cap only...not one across the tank and another

on the tap although thats an interesting idea. Maybe this schematic
will help.

Howdy,

Oh, ok! I have seen a tapped down band spread capacitor circuit so I assumed...

I wonder why they did that? Oh, looking at it the another way, the grid impedance loading the parallel tuned circuit is transformed by the turns ratio. Probably to provide some voltage gain from that stage.

If the capacitance of the grid is negligible, then the resonance is determined by the inductance from the portion of the winding paralleled by the variable capacitor.

If you want to include the grid capacitance in parallel with the variable capacitor, multiply it by the turns ratio. Otherwise the solution is essentially the same.

So what about the 'top' portion of the coil being effectively in series
with the tank? Wouldn't that affect the tank values?

Tnx?

I pulled mine off the shelf today to dust off the cobwebs. Much to my chagrin I found the tuning capacitor almost frozen stuck. For those that aren't familiar with the construction of these there's a lot of nylon? bushings involved.

I suspect lubrication may be the culprit that causes the nylon to swell up. I was finally able to get it loose enough to where the vernier doesn't slip although it still feels very tight.

Too late for me to avoid lubrication but I thought I'd pass this along for the next guy.

Howdy,

Maybe not. Imagine the top portion disconnected, it would have very little effect. It's no more than a small capacitor swamped out by the tuning capacitance.

I think if the grid capacitance times the square of the turns ratio is small compared to the tuning capacitance, it can be ignored. Because there are other strays that will require a bit of pruning in any case.

The most significant effect would be when the tuning capacitor is at its minimum value. So it's here that it may effect the design of the inductor, requiring a bit less inductance for the desired upper band limit compared to the other tuned winding.

There are no padding capacitors on that schematic. So I suspect there are seperate tuning capacitors for each tuned winding on the transformer. Because of this I believe it's not that critical. You could measure the grid capacitance with the tube mounted in its socket on the chassis. Then add that capacitance times the turns ratio to the value of the tuning capacitor when you calculate the necessary inductance value.

Or build the coil so you can stretch it (slip a few windings further apart) a little once the thing is running. Then secure them with a bit of wax.

73,
Grumpy

Howdy,

Heh! I didn't look at the url for that schematic, it's an SW3!
I love National Radio gear. I had two HRO-500's, sold one, and
there's an FRR-59 in my basment. I regret having sold my pristine
RBL receiver which beat the pants off either the HRO-500 with LF10
or the Racal RAL7 with RA237 for LF/VLF work. My highschool's club
had an NCX-1000 which I lusted after... er, but only in my heart.

But back to the SW3. I recall padder capacitors mounted on the
top of the RF stage coil former. I don't know the value of the
dual gang tuning capacitor but armed with that, Wheeler's formula
and these sites, you could calculate the effect of the grid circuit
to some extent.

Well that's sad. I doubt it's nylon which was invented in 1938,
maybe phenolic? Wood filled phenolic which swells... ugh!
Maybe you can rinse it with solvent then dry it out so it will
shrink back to nominal dimensions. The rest of it is constructed
of isolantite and brass which solvents won't hurt.

Could be phenolic but it really seems like a plastic of sorts. Hard to tell. The front bushing is where it got tight and there's no easy way to get it out for a thorough cleaning.

Only the bandspread coils have the trimmer on top and thats basically to set the rough frequency. The main tuning then becomes a bandspread tuning. I've forgotten all this stuff - I'll have to look back at my stuff...maybe the trimmer falls in series with the main tuning caps.

Anyway, thats just an example that came to mind. I've seen others doing
similar tricks for main tune/bandspread tune using the same cap but with
a different coil configuration.

One thing to be a bit careful about is including the coupling between
the coil sections.  Since I don't know how those particular coils were
designed, I can't say for sure, but in general the coupling between
pieces of the coil isn't as high as you might think.

You can make a good estimate for typical HF single-layer air-core
solenoid coils just using your favorite coil calculation.  For
example, consider a coil that's one inch diameter, two inches long, 20
turns per inch, and tapped at the 30th turn (1.5 inches) up from the
bottom.  Then the whole coil is about 16.32uH, the 1.5" part is about
11.54uH, and the top 0.5" is about 2.63uH.  If the coupling were
perfect between the sections, I believe the inductance of the whole
would be about 11.54uH + 2.63uH + 2*sqrt(11.54*2.63)uH =3D 25.19uH.  At
16.32uH for the whole coil, the implied coupling coefficient between
those two sections is only about 0.20, and you need to be careful to
not think of the tapped coil as simply a transformer with a 3:1 turns
ratio, with implied close coupling between the sections.  (This also
illustrates why you can short out turns of a tank coil without totally
killing the net inductance...)

I trust if I've hosed the calculation too badly, someone will point
out the error of my ways.  ;-)

Cheers,
Tom

Howdy,

That's an excellent point. I expect that the sections
of the coil in question will not have very good coupling.
I hadn't considered it! I calculate the same inductance
values.

Bah! In my previous posts the "(sqrtL*C)" should be "(1/sqrtL*C)"
Heh... with a pencil and paper the formula turned out right.
I noticed this when I calculated the resonance of the two
values 16.32uH and 11.54uH with an arbitrary value of 50pF
just to verify how I thought things should be.

So from this I gather that the extension of the coil
connected to the grid circuit will have even less
effect on the tuning than I expected.

The Easy Teenage NewYork method of solving this would be
to put the problem into SPICE with the estimated coupling
coefficent of 0.2.

I've never liked shorting turns to reduce an inductance.
Seems like an avoidable source of some losses no matter
how you slice it. But for some long coils, like antennas,
it works ok. I guess.

I saw something in the last year or two about building a PC that runs
entirely on 12V and with low power consumption. Does anyone know
where I can find that article or website?

Thanks in advance...

...ted, KC7PM

That is a VERY weird capacitor. First of all it tunes through 270
degrees of rotation using a unique shape of rotor plate, stator plates
are triangular. Second weird thing is that the shaft bearings are
insulated from the frame, the rotor is grounded at a single point, a
flexible conductor running though the hollow shaft and grounded at the
rear of the rotor. I have a single gang version of that capacitor that
was 'featured' in the one tube regenerative receiver from the A. P.
Morgan 'Boy Electrician' book from the 50's. National did make scales
for their velvet vernier dials that went through 270 degrees of rotation
for use with these capacitors.

IIRC the SW3 used a dual 100uuf capacitor. It's a weird one that
tunes through 270 degrees of rotation.

Agree with WEIRD. After goofing around with it I had a heck of a time
getting everything realigned. Never did see a way to completely
disassemble it.
Whats your take on the type of insulating material?

> where I can find that article or website?

I think I remember something in QST awhile back, but I'm sure it was more than a couple years ago. IIRC, the author had a bad battery pack for his laptop, so he rebuilt it by removing the bad section and providing a connector to bridge the remaining batteries (for charging) and to power the laptop externally with a 12VDC supply.

Hope This Helps,

-NM

I heard a guy on a radio program just last week describing a small
notebook - about half to 3/4 the size of a normal one. Uses flash
drives instead of a hard drive. Said power consumption wasn't much more
than a well equipped cellphone. Sounds incredible, don't know if such a
thing is actually on the market yet. Just FYI.

You might take a look at
http://www.idotpc.com/thestore/pc/viewCategories.asp?idCategory=68
to see what they have to offer. Apparently it's not difficult to get
a 12 volt input computer power supply that fits one of the standard
compact cases.

HTH,

MacBook Air, Asus EEE, Acer 100, and a whole bunch of no name clones.

If you are in the UK, Elonex ONE, which sells for 100 quid.

Geoff.

The thing you want is the Asus EEE PC:

http://eeepc.asus.com/global/products.html?n=0

Don't bother with the Windows version - it makes it almost as expensive as a full-size laptop, and suffers from all the multitude of Windows problems. The original version runs Xandros Linux, and there's a /huge/ range of software available at no cost, including lots of electronic design and ham radio programs.

I use one for a mobile packet station, for logging and for morse or teletype modes.

Bob

I have witnessed 50 or 70 year old variable capacitors of
low-to-middle grade construction where I swear it's the metal

that's swelling. The spacers between plates seem to have expanded or contracted so that while the rotor/stator mesh is centered at the center of the capacitor, at the ends the rotor and stator are nearly touching.

Others tell me this is well-known but I still don't have any understanding of why metal would shrink or grow with time.

Trying to figure this one out, The choke has two small wires
going back to the circuit board to a potentiometer and some
unidentifyable ICs. The pot is sealed with RTV. I am guessing
this is for overcurrent sensing. If I could verify this I would like
to set it to activate at about 10 amps.

Where there's pot metal involved it certainly swells up.  Thats a
scourge in 1920s sets that use pot metal pulleys, brackets and capacitor
frames.  My understanding is that it is due to reaction/corrosion
between the various metals in the 'pot' mix.

This sounds like what may have happened to some old drives I had.
A guy gave me half a bushel of the things telling me he thought they
would work if I cleaned them up. I bet he had gone through the other
half a bushel trying. I was able to repair a few by drilling out the
holes
and inserting the brass ferrules removed from old pots. I hope this
proved
to be a good fix and the guy that bought them from me isnt cursing
me too loudly.

Jimmie

Well, my metallurgy knowledge has always been particularly poor.

With the problem variables I have on the shelf, the issue isn't
necessarily
the spacing between adjacent plates but the cumulative swelling
over a dozen or more spacers.

I have discovered that by disassembling the caps and grinding
every 3rd or 4th spacer down by a smidgen that the result seems
just fine.

This only helps on the capacitors that can be disassembled... but the
pot metal spacer problem seems to be worst in the kind that can be
disassembled.

Some later top-quality air variables I have use something that
is either welding or silver brazing to space/hold the elements on a
solid rod. These do not have the spacing problems. They're pieces
of beauty...!

Tim.

And a second thought is see the same thing on the second stage, where the top portion of that tank is in series between the tank and the control grid... Redraw that circuit in your head so that the top portion of coil is bent over at a right angle to the tank... I wonder if the grid to cathode capacity is too high for comfort and the series section of coil is for taming that... We do that for amplifiers on 10 meters where the plate capacity is too high for comfortable tuning... A small series coil between the plate and the tank calms that down...

Hi all,

A few things have happened since my last update. The homepages are to be found at http://web.telia.com/~u85920178/ where there are some 250+ projects, many with PCB foil patterns in BMP format, 250 dpi. This means you do not need any special software to view it.

The lastest project was DIY transformers. the link is http://web.telia.com/~u85920178/power/diy_transformers.htm and it uses those cheap transformers from http://www.kjell.com

I also did an article on diode switching basics, but this I also translated into Swedish and sent to the SSA for publication. The URL for the original article is http://web.telia.com/~u85920178/data/diode_switching_01.htm

The old messageboard is now defunkt - kaput - deceased. Instyead I have a nice new forum at http://sm0vpo.wahlberg.cc but you should bookmark the address http://web.telia.com/~u85920178/board.htm so that I can again change in the future. The new board is hosted by Magnus Wahlberg in Eskilstuna, and a fine thing it is too. Message at the bottom do not just drop off into space. Old messages stay there until I or a moderator deletes them.

Perhaps you never thought about it, but the old formula for frequency = 1 / 2 x Pi x Root(LC), and the only variables are F, L and C. So for any value of F you can build a table of Root(LC) values. For example an index of 1MHz = 25000. If you divide 25000 by 250pf you need 25000/250 = 100uH for resonance.The value for 2MHz is 6250, so if you subtract one index from the other, you can work out the variable capacitor you need to track tuning between the two frequencies. The article is at http://web.telia.com/~u85920178/data/tune_01.htm

Future articles are many and I have several that are all nearing completion. Progress is interrupted by a speeding ticket with one of those stooopid speed cameras. Now I know how they function I will shortly be publishing a speed-camera blocker. I will also offer a few in kit form, until I get my 2400:- back.

I have also finished a "Generating 230V AC Power in 5 Minutes" video film. The link is at http://www.youtube.com/watch?v=t3yvdXIjGSo

Best regards to all from Harry - SM0VPO

They are a great little PC at a GREAT price. They are not selling so
hot,
Maybe the price will get even better.

Jimmie

Hey all:

I tore down a transformer I got from ebay it was a Zenith TV power
transformer from days gone by. Re wound it with 17AWG wire on the
secondary and primary. It powers up my 4-1000A filament nicely with
7.25VAC from 120VAC mains. I used a penta-filar winding on the
secondary. Shimmed the bobbin in the core window with some 1/8 thick
virgin teflon. Epoxied the windings to the bobbin. This was a 240VA
transformer and now is a 83watt buzzer / 157watt filament transformer.

So what is the cheapest I can gits away with sealing these laminations
from buzzing, I used up all my epoxy sealing the windings.

wow so many of these replies are wrong..

in almost all cases, RF path losses are RECIPROCAL.

(It is very unusual for RF path loss to be non-reciprocal.

Mark

I agree. But, one thing that should be proven is that both modules
are working as intended. The one being used for the remote
application *could* be defective. Swap modules and see if the
receiving problem also switches locations, or remains the
same.

Pete

Hello,

There should be a reciprocal relationship between the modules regardless of height, antennas etc. as long as TX power and RX sensitivity of the modules are the same (which they appear to be).

The modules are unlikely to have very good input filters at 868MHz, so any adjacent channel interference (GSM etc.) is likely to cause the out of balance behaviour.

Try heading in a different direction outside, or go somewhere else with your experiment.

For your real world application, are you likely to have any site close to adjacent channel transmitters (cell or broadcast) ? If so, think about a decant front end filters. This could be costly, but might save you...

Regards,

Mark

I've sealed rewound filter chokes by dipping them in a bucket of
polyurethane varnish.

news:159dee31-5436-4f46-ae9d-48214eec09ca@k37g2000hsf.googlegroups.com...
Hello All

We have a propagation issue that is confusing us. We have two 868MHz modules on test, each capable of 500mW transmission.

We are testing to find the range of communication. We are testing them as follows. One remains in our office while the other is taken to the street outside. we are communicating charecter strings such as "Im at the lamp post number 1" etc. There is somebody at each end sending text strings in a continuous conversation. There is no protocol, error checking or error recovery.

What we have repetadly found is that the radio in the office can receive long after the radio in the street has stopped receiving. (The person with the radio in the street is moving away from the office.)

The radios are the same and the power supplies to the radios are the same. Indeed switching the radios gives the same effect.

The propagation paths between the two radios are the same in terms of distance. However the radio signal transmitted from the office travels through walls first before then traveling through open space. Its the opposite for the radio in the street, firstly traveling through space and then through the walls in the office.

We did think we had identified an interfeering source in one direction (when moving away from the office) so we started moving in the opposite direction. We found exactly the same effect.

Are we getting interfeerance from GSM, ISM or Paging?

As far as GSM bands go in Europe 890�915 MHz OR 1710�1785 MHz So these shouldnt be our problem.

ISM is where we intend to operate and the greatest band occupancy should be 10%. So we should get communication even though we would get some interfeerance.

Paging - well this has very much gone out of fashion in Europe. But even if it was the cause then wouldnt it be intermittant communication. We have a constant problem.

Can anyone shed light on this phenomonon? Is it an issue of wireless propagation that Im not familiar with or is it Interfeerance?

Best regards, and thanks for any input.

Denis

its interesting that a commercial company would bring a problem such as this to a bunch of amateur radio operators... true some of the amateurs may be professional engineers, but the remainder are not! I guess that in today's market place we try to gain information on the dirt and cheap way.

What is the modulation type and data rate? Could be a delay spread
issue. Maybe the outside unit is receiving a reflected signal from the
surface of a nearby structure and is experiencing inter-symbol
interference that by chance the base unit is shielded from. This would
occur only if a high symbol rate was being used.

>

Nah, that's ok. Every one of us occasionally runs into an unusual situation. Then one can either stew on it for days without getting to the ground of it, or ask. IMHO it is a sign of maturity if somebody has the guts to say "Hey, guys, this problem here really has us puzzled".

That is especially true for EMI cases and this sure looks like one. Sometimes a brief hint by someone who has been in the trenches for decades can get things going again. And most older ham radio operators had that exposure, fixing the neighbor's electronics because their manufacturers messed up.

The OP said that he did that, and the problem remained. It's certainly a desensing problem due to local interference at one end. That's the only possible cause.

A good trick for the lams is clear nail polish as you reassemble them.
Just a quick wipe, as it'll spread as you squeeze in the last few lams
under a "Quick-Grip" clamp.

Cheers!

I'll second that.

Varnish is the best thing. Warm the varnish and the
transformer first before you dunk it. That will reduce
the viscosity and improve penetration. A little thinner
in the pot may help too. Vacuum/pressure impregnation is
better than dipping... but dipping can work well on a buzz.

There is even special dipping resin to reduce noise that

leaves the part looking like it's been dipped in a candy
coating. It's a soft, rubbery, epoxy coating.

Oh, and the teflon isn't so great as a shim. You might try
nomex paper, G-10 PC board scraps, fish or kraft paper even
typing paper, calendered cardboard (like shoe box cardbord)
or wood. Teflon will withstand the heat but it tends to
cold flow which makes it dimensionally unstable. The amount
of mechanical force between the core halves can be surprising.
Though in your transformer teflon may be be OK. In a choke
it can be a source of bewilderment as the gap decreases. Yes,
I've had this happen.

Any material that will soften when it's hot, like perspex/plexiglas
isn't a good choice either. I found this in an inductor for a
10KW boost converter that an otherwise reliable supplier built
for me.

For varnish, I like Dolphs (Von-Roll.) Failing that I use
marine spar varnish. Some varnishes are corrosive to copper
and over time will cause windings of fine guage to open if
any copper is exposed.

What amateur band covers 868 MHz? Did we get a new one? I'll have to
order another transverter, I guess ;)

Well, to get this post be on topic, does anyone know of a good source
for some SPDT coaxial relays good at 902 MHz and good for 350 Watts at
902?

Scott

This would work even better if you could pull a slight vacuum
on the bucket to get the air bubbles out. I believe that's how
the manufacturer's did it. There was a thread on this over on
AMFONE.NET a few month's back.

Uh! Sorry Ray, it was near 2AM and I misread this. Of course
there's no gap in the core it's a linear AC transformer. No
DC in the windings and so no gap.

Usually I'd do everything I can to reduce any gap, inclduing
interleaving the laminations, to reduce the magnetizing current.

I just wasn't thinking, that happens sometimes.

I recently posted a similar message to the boatanchors newagroup, but I have had no reply, so I hope that perhaps a different readership of this newsgroup might be able to help.

At a recent radio rally I picked up a Hallicrafters S-118 receiver. It's a bit tatty, but I was interested since I have never owned a valve (tube) receiver. I've located a scan of the service manual on the BAMA website, but the schematic was unreadable. I've found a number of US websites which sell the manual, but the cost plus postage is about the same as the rx cost! I will go this route if nothing turns up.

If anyone can help with the schematic or information on the power supply I would be very grateful. I have no idea what voltages the power supply is supposed to generate, but one idea is to replace the US transformer with a UK equivalent. The power supply appears to have a semiconductor doubler on the output side. I am quite happy to remove this and use the correct secondary voltage from a UK transformer. I may be possibly offending the purists, but I am happy to replace as much of the PSU as necessary just to get the rx going again. I do have some high voltage transformers in my junkbox despite never having constructed any tube equipment.

During the various searches it appears that the S-118 has a mk1 and mk2 version. If anyone could explain the difference (so that I can order the right manual) I would be grateful

==
Suggest you keep the rx as is an feed it with 115-120 V ,either from a
variac or a sturdy 230/240 V transformer with a centre tap , using only
the primary winding as an auto-transformer (not using the secondary
windings) (Large) transformers can often be found at Junk sales or flea
markets . Another possibility is using 2 transformers ; one being
230/240 to 12 V or about and the second one 230/240 to 24V or about
By connecting the the secondaries you can get 115/120V.

Of course you have to ensure that the transformer(s) can handle more
than 100 W to be on the safe side . The Hallicrafters rx will highly
likely not consume more than 100 W

If the rx has not been used for considerable time ,the electrolytic
capacitors might have to be reformed . Do that (preferably) with a
variac or with a few transformers with say 12 -24 V secondaries,
starting with say 12 V connected to the rx power input ,after a while
increasing the voltage by series connection with another low voltage
secondary ,either from the same or a different transformer (ensure that
phasing is OK by checking output with voltmeter) .
To minimise power required while reforming the electrolytics you can
remove the valves(tubes) (but of course not the HV rectifier valve if
fitted

There is 1 potential snag using equipment designed for 60 Hz (USA) on a
50 Hz supply system . If the transformer of the rx is marginal capacity
wise , it could become rather warm when connected to a 50 Hz supply
system , because the higher frequency permits less transformer iron.

Note: During the valve(tube)equipment era ,aircraft required AC .
To minimise weight the transfomers used had to be as low in weight as
possible , that's why the onboard supply system operated at 400 Hz.

Good luck with your vintage RX

Frank GM0CSZ / KN6WH

If you have bolts thru the lams have you torqued them to the point of twisting them off? If you haven't you might want to loosen then and add some more varnish to the lams while they're loose and then torque them. Another possibility: Many of the transformers in microwave ovens have a bead of weld across all the laminations and I've seen this on rectifiers used in Telco applications. Keeps them quiet and I and has some negatives like letting line spikes thru but on a filament that is meaningless. Lam eddy currents area dead issue as I've heard that the old Bell Labs had accepted this practice.

I had a 30S-1 with minor buzz but when I added 100 volts to the screen the hum was about to drive me nuts but torquing to lams solved the problem, I twisted off a couple of bolts.

Hmmm!

Bolts through the laminations should have insulators (usually fiber board washers) under the heads. Just one end will do, there's no need for them under the nuts. But shoulder washers are best so the bolts don't short any laminations together deeper into the core.

If uninsulated the bolt can form a poorly coupled shorted turn and that in itself can cause noise, heating of the core and the hardware as well as spray flux around where you wouldn't have expected any. How bad it is depends on the locations of the holes in the core.

A bead of weld across the ends of the laminations won't add to the eddy currents significantly. Steel isn't a great conductor. The weld's cross section is small and it's very poorly coupled to the primary.

Why would a weld across the laminations let line spikes though?

Hi Frank,

thankyou for your reply. I already have a Maplin 240->120V autotransformer which should do the job nicely. The radio has been somewhat hacked around with and did come with a heavy and ugly UK transformer wired as an auto-transformer. It is now removed and will be used in a future valve based project.

From the poor schematic which I have the secondary goes into a semiconductor diode voltage doubler. There is then some kind of resistive chain which I assume generates the voltages for the screens of the valves. I really need a clear set of schematics to see what values should be found.

The valve heater voltage part of the schematic is a mystery. The valves are 4 x 6.3V and 1 x 12.6V, but the schematic suggests a different line up of 2 x 6.3V and 3 x 12.6V. The valve ids are not readable on the schematic. Perhaps the schematic was from a mk1, although it is supposed to be from a mk2.

I have now removed all the components which make up the voltage doubler and the main triple capacitor is now isolated. I will try to reform it (from a variable DC supply) and check that it is still working. The resistors in the chain are clearly not originals. They may have been changed when the auto-transformer was added.

Grumpy
Years ago in 93 or so on a Telco fiber system by Alcatel we took severe hits when the air conditioner came on and it was traced to the station rectifier. The Gould rectifiers had a weld bead and when we replaced them another make which I can't recall that didn't have weld beads the problem went away. Its quite strange since the rectifiers floated big batteries but a vco in system was sensitive to the spike. After doing some research I found an explanation that I can't recall because I was too busy with other problems and mine had gone away. Alcatel spent several hundred thousand trying to find the problem and I stumbled on to it by shear luck.

> I tore down a transformer I got from ebay it was a Zenith TV power transformer from days gone by. Re wound it with 17AWG wire on the secondary and primary. It powers up my 4-1000A filament nicely with 7.25VAC from 120VAC mains. I used a penta-filar winding on the secondary. Shimmed the bobbin in the core window with some 1/8 thick virgin teflon. Epoxied the windings to the bobbin. This was a 240VA transformer and now is a 83watt buzzer / 157watt filament transformer.
>
> So what is the cheapest I can gits away with sealing these laminations from buzzing, I used up all my epoxy sealing the windings.

This might be a little "far-out" but, besides just buying more epoxy and just doing it right, maybe you could find a can or metal box, put the transformer into the box, and fill the box up with enough sand that you have 1-2 inches all around the transformer, and that might muffle the buzz. You'll need to worry about heat dissipation through that sand which will act like an insulator, but if you are on the air only a couple of hours per day, it should not get dangerously hot (however, many of the old hermetically sealed transformers were burried in a waxy-tar that was quite hard at room temperature).

Your other option is to figure out some clamping arrangement so that the laminations are held close and tight.

Re-winding transformers is fun, but next time you want some off-beat voltage, maybe scrounge up higher voltages (eg. car battery chargers) and use either a variac or power resistor (with sufficient heat dissipation) to bring the voltage down to where you want it and save yourself the headaches and earaches. Or, don't take the laminations apart but feed the wire (stranded) through the holes that are left.

Or, other kludge-cheapskate approaches.

Good luck.

Denis,

I agree with some of your previous posts - the outside receiver is
likely being desensed by a strong signal, perhaps away from or a
harmonic of the frequency you're using. I suggest trying the test away
from town and at least 10km from strong transmitting towers. Let us
know what you find out - may help those of us who do UHF/VHF mobile/
portable hamming.

As a ham I have NOT PROBLEM with the commercial community asking
questions on a ham radio group - we can ALL learn from this.

Cheers,

Dick Post, N7EMW

i was thinking about that...but no....

all the multi-path paths are reciprocal as well,,, so whatever the
delay spread is one way should be the same the other way.

****
I don't know why I don't get the > on your response, but whatever.
He can get some feel for what is going on by taking *both* radios outside
near his office, and walking around. He should be able to find a particular
area that has poor reception. I don't buy the explanations for antenna gain
and multipath, they should affect both directions of transmission equally.

Tam

Howdy Hank,

Thanks for the follow-up! Perhaps they used a voltage regulating
transformer. I think some of the telcom rectifiers used them.
I know some mainframe computers did.

It's still a curiosity to me. Though I've seen enough occult
behavior from wound magnetic devices that I wouldn't discount it,
I'm tempted to wonder if there's another variable that was
coincident with the welded laminations.

It's not so far out of a suggestion. One of my Zenith console radios has some remote control solenoid mounted inside a metal box that's lined with rubber.

The sand is a pretty good thermal conductor (compared to air), better than epoxy. In fact they fill the cheaper type of epoxy potting material with coarse quartzite or powdered limestone to improve its the thermal conductivity. It's the air trapped between the grains of sand that provide some thermal insulation. Mixing sand with epoxy or oil fills the interstaces which would otherwise be filled with air.

Some one mentioned coating the laminations with nail polish as you stack them up to glue them together. Either that or little varnish would most likely have prevented any buzzing laminations.

Not taking the laminations off is a good suggestion too if it's possible. For instance microwave oven transformers just chisel off the secondary and wind a new one. Though for smaller transformers that often isn't possible.

I have always dunked them in varnish but only got some success with
this by
drawing a vaccum then applying pressure. I used an old compressor
from
a refrigarator to do this. The tank was made from from pipe and
fittings. The best
results I got was winding the core on a block of wood cut the same
size as
the core wrapping the wood with cardboard then windng the coil then
pushed
then put the core together. I was 18 at the time and a very talented
man
named Olin Griggs helped me with this project and let me use his
shop.
Olin was a retired engineer that had worked for GE at their
Bloomington plant.
Since then the onl transformers I have wound that havent bussed to
much
was by modifying a ready built transformer. USually this meant one
that I
on which I could keep the primary winding intact. Lately I have gotten
interested
in SMPSs for doing this sort of thing. It is very easy to see why
industry has
has made the move to them.

Hey Grump
A transformer is one of the simplest electrical machines and pretty well understood in the classical design but when some of the parameters are changed we don't have much experience or investigation and probably wont. Hot swappable rectifier modules have made transformer based rectifiers uneconomical kinda like carburetors and fuel injection. If you have the time, check with some of the old time designers of transformer rectifiers. Let me now what you find out. I had some notes but those are long gone.

Since most of the posts, in their "EXPERT OPINIONS", relate to your
receiver being "de-sensed", do you have a way of negating/affirming this?

Begin there, and we can get down to "real problems!" :-) i.e., a
wide-band field strength meter, freq counter, etc. will either make all
this "right" or "wrong."

Regards,
JS

Desense is definately a possibility, but I still believe that it's at least AS good a chance that it's a standing wave issue on the office end. Others have said to take the 'office' radio outdoors and test the setup that way. That's a good (and simple) test.

Howdy Hank,

I've been designing switch mode magnetics for about thirty years now. The more I learn the less I know. It's true that the principles are well known but the implementation is a morass of compromises. At the power level many of my designs operate at, second and third order effects can suddenly become serious and unexpected design complications. Some people enjoy puzzles. I guess that's why I like designing this sort of stuff.

I've worked on a lot of weird stuff, big cap charging supplies, pulse compressors, very high voltage or high current, and tiny stuff with extremely low noise outputs. But I don't have much experience with line frequency magnetics beyond EMI filters. As you say there's not much call for it now. But unfettered by all the weak components the big iron can support amazing overloads, so I think there's still a place for it. At least for now. The cost of steel and copper (and the transportation costs) for such heavy beasts is certainly making them increasingly less attractive.

Lately I've been working on equipment in the 10KW-60KW output range switching at 75KHz range. The whole system weighs much less than just the line frequency transformer that would be required alone.

The only big iron guys I know are now retired or dead. And the companies I've dealt with that make that stuff tend to have very little engineering staff, not much new going on, (other than some efficiency improvements from amorphous cores) they just crank out the product in cook book fashion. I think nuances of it may soon be a lost.

73

I'm /still/ more inclined towards a desense problem - cities are astonishingly noisy these days throughout the RF spectrum. I've recently had 4.9 GHz data transmission problems that were eventually traced to a harmonic of a nearby surveillance TV transmitter!

Desense caused by out of band signals if of course possible when we talk about such toy receivers as most wireless LAN or wireless headphones are.

However, since the 868 MHz band is a non-licenced band, it is quite likely that there might be other transmitters (e.g. wireless headphones) in the area of the moving transmitter, but not near the office transmitter.

Give a spectrum analyzer to the moving station operator to monitor the interference level in that frequency band, when the moving transmitter is off. A scanner receiver with a decent signal strength indicator might even suffice.

>Desense is definately a possibility, but I still believe that it's at least
>AS good a chance that it's a standing wave issue on the office end.

This is out of the question for any single frequency half duplex connection, since the path would be reciprocal. In a full duplex dual frequency point to point system between two _fixed_ station, this would be definitively possible. Even in this case, moving the other station by 10-30 cm, you would find a spot, in which there is a good connections both ways.

Based on my experience at 1297 MHz with a narrow band (16 kHz) signal in urban environment, you definitively have a lot of multipath nulls (several nulls every meter), For speech communication, this is not much of an issue, the faster you move, you have hundreds of nulls every second and it does not much affect the readability of the speech. The only problem is that if you stop at a traffic light, you usually will end up in a multipath null and the communication is broken, unless you can slide the car a few centimeters.

>Others
>have said to take the 'office' radio outdoors and test the setup that way.
>That's a good (and simple) test.

The OP did swap the radios, but he did not tell if the power supply was also swapped. If the office power supply was faulty and the office transmitter could not deliver the nominal power, this could explain the situation.

Paul

hey all:

>A good trick for the lams is clear nail polish as you reassemble them.
Just a quick wipe, as it'll spread as you squeeze in the last few
lams
under a "Quick-Grip" clamp.

I could go to the nail shop get a peddicure and coat my lams at the
same time. A great idea if only I could handle the fumes.

>Varnish is the best thing. Warm the varnish and the
transformer first before you dunk it. That will reduce
the viscosity and improve penetration. A little thinner
in the pot may help too.

I lucky I can stand the effects of epoxy but no way varnish. For nail
polish or varnish I gots to gits me a up or down draft venilator
exhastt system.

>If you have bolts thru the lams have you torqued them to the point of
twisting them off? If you haven't you might want to loosen then and
add
some more varnish to the lams while they're loose and then torque
them

Thanks I retorqued them and that reduced the noise by 6db. Now I have
a less effecient buzzer

>Bolts through the laminations should have insulators
(usually fiber board washers) under the heads. Just
one end will do, there's no need for them under the
nuts. But shoulder washers are best so the bolts don't
short any laminations together deeper into the core.

Good idea I seen many a transformer that had fiber spacers over the whole length of the bolt plus fiber washers..

>put the
transformer into the box, and fill the box up with enough sand that
you
have 1-2 inches all around the transformer, and that might muffle the
buzz. You'll need to worry about heat dissipation through that sand
which
will act like an insulator, but if you are on the air only a couple
of
hours per day,

I likes this one, but I gots alot of kittie litter that comes from some place in Arkansas, it is mostly quartz and some other trace minerals.

The only big iron guys I know are now retired or dead. And the companies I've dealt with that make that stuff tend to have very little engineering staff, not much new going on, (other than some efficiency improvements from amorphous cores) they just crank out the product in cook book fashion. I think nuances of it may soon be a lost.

Yes lams are going the way of the dinosuars. Maybe that's why they cost so much looky the price of a good audio output transformer for a tube audio amplifier and they go up to at least 20Khz.

Your other option is to figure out some clamping arrangement so that
the
laminations are held close and tight.

Yes I think I will put together a vise of sorts. Custom made to fit the transformer.

73 and thanks for all the good information.

n8zu

==============
Followed this thread with great interest .
Reason : I have an Astron RS-50A , 13.8V -50 Amperes unit for 220V-AC
input which is buzzing heavily. Upon switch-on the group circuit breaker
in the house sometimes trips due to the high switch-on current surge .
This can be overcome by adding a soft start circuit which initially puts
a say 25 Ohms-50Watts resistor in series with the primary transformer
winding ,shorting this resistor after a second or so.

However I fear that the main reason for the buzzing is that the
transformer (of US origin) was designed for 60 Hz ,whereas here in the
UK (like in all European countries) the supply frequency is 50 Hz.
Can someone on this NG please confirm/reject my suspicion.

Another possible reason could be that the cabinet sheet metal which is
very close to the transformer is vibrating (transducer effect) .

TIA for any constructive advice/opinion

Frank   GM0CSZ / KN6WH

Frank I emailed XXXXXXX's address to you. He designed the Astron Power
supply.

Jimmie

I suspect that you are right.

If I recall correctly, transformers designed for 60 Hz can suffer from
excessive quiescent current flow in the primary windings, if used on
50 Hz... the windings don't have enough inductance. Also, because the
frequency is lower, the transformer will be drawing more current
during the brief intervals (100 times per second) when the power

supply rectifiers are conducting and recharging the filter capacitors... the abrupt changes in the current flow and the resulting magnetic-field changes may be causing the windings or laminations to move around and buzz.

Transformers designed for 50 Hz service generally work OK on 60 Hz... it an "easier" job for them.

Transformers can also buzz if there's anything on the same mains circuit which is generating harmonic currents (e.g. other linear power supplies). Toroidal tranformers can be prone to buzz or hum if other loads on the mains line are drawing current from the line in an asymmetrical fashion and thus creating a DC offset on the mains... the toroid goes into saturation.

```

Do you have GloBar resistors in the UK? These are high cold and go lo
with current. they used to be very popular in TVs over here.

I think some of the PC power supplies have a surge suppresor in them.
I you have some old power supplies around you coulld be in business.

Actually "transformers" that carry DC (IE: filter chokes) have a gap formed by putting ALL the "E"s in one direction and ALL the "I"'s in the other.

For transformers that carry SOME dc (audio output transformers) group the "E"'s and "I"s in bundles and assemble with a few groups of bundles going in opposing directions.

For transformers that carry ONLY dc (power, filament) alternate each lamination so no two in a row go the same way.

I meant for transformers that carry ONLY AC!  oops!

Yep, It's all about core saturation.  A large utility
transformer can be saturated by just a few amperes
of DC.  Which is one reason improvements in load current
THD are important.  Zero sequence currents and all
that jazz.

Howdy,

I think I would measure the line current with no load on the transformer. Then let it idle a while, maybe three hours, then give it the finger test. If it's not warm and the magnetizing current is small, I'd then run it with a heavy load and check it again. If it's not stinky hot (the winding is below about 110C more or less) I'd say it's OK at 50Hz and the breaker tripping is from the inrush current.

There's some inrush current charging the core. That's not a defect though, it's just how things work. The first half cycle peak might be five or more times the peak magnetizing current. The inrush current charging the capacitors is more prolonged. Depending on the curve of the circuit breaker one or both might be to blame.

So if the soft-start circuit works for you just monitor the temperature of the transformer. If it's reasonable don't worry. Then look elsewhere for the cause of the buzzing. The cabinet sheet metal you should be able to quiet with the palm of you hand...

Ok, here's one crazy idea. The inrush current is mostly on the first half cycle so it's magnetizing something, maybe the cabinet who knows what, which is then a more efficient transducer. If you soft start it either doesn't magnetizing the part or perhaps degausses it.

Hello all.

I am trying to build a simple repeater system. This is how I have it
set up:

Kenwood TK-7102 receives on on frequency #1 and is connected to Yaesu
FT-1802 which transmits on frequency #2.

The Carrier Operated Relay output of the Kenwood is connected to the
PTT input on the Yaesu. This works perfectly.

The problem is with the audio. I tried connecting the audio output to
the Mic input on the Yaesu. The result is the audio with a horrible,
high-pitched warble in the background. Any ideas?

I've tried connecting to different audio outputs that I can find in
the service manual, but they all have the same problem.

Thanks!

Philippe Signoret

You may have a ground loop problem. I suggest the use of an isolation
transformer between the transmitter and receiver. Also pay attention
to signal levels, an attenuator be may be required to achive the
proper audio input level to the transmitter.

Jimmie

Hey Ken & Grumpy
I started a new thread from the 7.5 VAC xfmr, because the subject has drifted. You guys mentioned a DC component in pole pigs. Sometime ago I heard that if an AC circuit had too many switching power supplies on it, that would cause the power company all kinds of problems. What were or are the problems and what was the evidence and what did the power companies do to solve the problem?

--
Thanks & 73

There could be transformer core saturation problems if large half-wave rectifier systems are used. In Europe old televisions had only a half wave rectifier to generate the anode voltage for the tubes. Fortunately, since the users would plug in their televisions both ways, usually both half cycles were loaded within an area.

In a balanced three phase system the neutral current cancel out and the neutral wire is loaded only then the phases are not equally loaded. For this reason, the neutral wire is often smaller in large underground cables.

Any full wave rectifier system generate strong odd harmonic currents each time the capacitor is charged.

However, when each phase is loaded with switching mode power supplies, which generate string 3rd harmonics, these harmonics do not cancel, but instead the 3rd harmonic neutral currents from all three phases add up, possibly overloading the neutral wire.

For this reason, at least in Europe, large power supplies must have a power factor correction circuit to extend the conduction angle during each half-cycle.

Howdy,

You're correct. The problem is mainly the result of many single phase capacitor input power supplies distributed across a three phase system.

In a capacitor input power supply, the line current takes the form of narrow spikes, because the rectifiers only conduct when the line voltage is higher than the capacitor voltage. Many SMPS have a capacitor input bulk supply at the front end. So the power factor is low and there is much harmonic distortion which includes triplens 3rd 6th 9th... harmonics. also called zero sequence harmonics (they do not rotate.) As they add in the neutral of a three-phase four wire system difference between their half cycles is a DC component. You can see that half-wave input would be the worst as Paul mentioned.

The solution reduces THD and increases power factor. For single phase input power supplies is either a large inductor which causes the current to look more like a rectangle. Or active PFC which is usually a boost converter with no input capacitor and a control circuit that causes the envelope of the current pulses follows the shape of the line voltage. Most often the active PFC is used but in low power supplies I've seen the big inductor approach taken. There are also other approaches like "valley fill" which force current to be drawn when then line is less than that needed to charge the capacitor. I don't see these used much.

Before PFC was common this was a huge problem in places

with many crappy PC and VDT terminal power supplies (like
big office buildings full of VT100's.) Sometimes the
neutral conductor which was sized smaller than the phases
because they expect little imbalance would burn up.
Sometimes the DC component would saturate big transformers
and they would fry.

Triplens can be blocked by ungrounded-wye or delta
transformer connections which keeps them out of the rest
of the facility but they still do their dirty work on
the secondary side. So it's better to not draw distorted
line current. With three phase input power supplies
a simple boost converter without the PFC control circuit
improve the PF to about 0.96 and reduce the THD to eh,
maybe 25% or less. The current in phase leg will be
rectangular.

This explanation could be too simple. And as always
some of it might be wrong! But does it answer your
question?

Thanks for your answer and explanation. This leads me to ask,
"Is there anything WE (the consumer) can do about it and if so, what?"

Thanks,

Geoff.

Thanks Jimmie. I'll check that and let you know. If I can, I'll run
some tests at my university where I can use the oscilloscope. I'll be
sure to get some images in case the transformer doesn't work.

Philippe

I would suggest the audio output level is way too high for the mic input of the Yaesu. Turning down the volume control on the Kenwood will bring down the level of the desired audio of the station being repeated, but there's probably some amount of inherent noise in the Kenwood's audio amplifier that isn't affected by the volume control. Since the Yaesu's audio input is far more sensitive than the Kenwood's speaker, you're hearing that noise.

A simple voltage divider would fix this. To toss out some values, maybe a 100-ohm resistor on the grounded side, in series with a 10,000-ohm resistor on the "hot" side, and tap the audio to the Yaesu across the 100-ohm resistor. I don't guarantee you it'll work but resistors are cheap & it's worth trying.

Do you have any method of ensuring the Yaesu won't get locked in transmit? (is there a timeout timer function?) Especially if you're using carrier squelch (not subtone), a spurious signal could leave the carrier-operated relay open and lock the Yaesu in transmit for a long time - possibly damaging the power amplifier. Not having a timeout may also be illegal in some countries.

Howdy,

It's something to ponder. It appears there's not
much the individual consumer can do.

I suppose a person could direct their purchases toward
devices that don't add to the problem. Like buying
PC power supplies with PFC. Early CF bulbs were pretty
bad but they're better now, though incandescent bulbs
will likely always be better in this one regard. Some
thyristor controls are still horrible, like dimmers and
thermostats. But I didn't see how the consumer could know
this.

Being aware of the energy savings when considering the
price of a product is something the consumer can do.
If it doesn't make economic sense then Ok, don't buy it.
But consider the cost of ownership as well when making
the decision.

Working to have power factor, total harmonic distortion
and efficiency ratings required on the equipment name
plate along with volts, amperes and watts. Is something
individual consumers could do. Sometimes the industry
needs a little nudge.

Keeping equipment in good repair can help. We nearly burned two taps off a 500KVA transformer at work. It was installed improperly which took some time to discover by way of insanely high THD under load. All that time the transformer was burning up power heating the taps and reducing efficiency of the equipment it supplied. This applies to farms and homes as well. Might prevent a fire as well.

From a ham perspective. Hmmm. perhaps build a PFC power supply for that big linear amplifier! Or use a PFC battery charger and run the shack off battery power

One last note, high PFC does not insure low THD but they usually go hand-in-hand because of the methods employed. A person could build a device to provide excellent PF and crappy THD. I've never seen any product that does this but it is possible.

I'm sorry I can't offer more or better suggestions.

There are small basic controller boards that you might find helpful for dealing with several issues.

Other issues to consider:

Think about a full time fan trained right on the PA and power supply and program TOT to 4 min max. in the FT.
Even then you may find your mobile getting way too hot even on the low power settings. Even to the point of melting solder.   The heat may not travel fast enough from the device into the heat sink and build up when higher power levels are selected. This winds up heating up the board too much
Also note the transmitter is spec'd at a drifty 10ppm.

Possible RF energy from the transmitter getting into the RX audio and thus into the TX audio.

Hams actually put more stress on a repeater than commercial users.

I was given this Weller soldering station. The display is not working. It does flash 888 on it when first turned on. The tip does heat up, but I have not determined if I can vary the heat or not. Also have an extra soldering pencle that plugs in it. Changed them to see if the display would light, but it didnot. Any hints on it ?

Also how do I open it up ? Screws under the 4 rubber feet ?

PF and THD can be a real problem when you generate your own
electricity.
About three years ago we installed a new UPS at work that went crazy
whenever we switch from line to generator. The installers said we
would have to install a generator 4X as large as the one we have to
take care of the problem. Considering our present generator was a
120KW unit going to 500KW was out of the question. We measured the PF
and THD for the input to the UPS and it was ridiculously high but the
installers insisted this was normal for the size generator we had.
Long story short we kicked them and their UPS out and got a different
one that worked flawlessly with our equipment.

I have same model unit with same exact problem. Yest it does regulate
the temperature. I haven't figured out the display problem either and
the thermistor in the iron seems to "ohm out" properly. Let me know what
you find. I never could find schematics for it. I used it just today on
a PIC project. Shame to throw it out, but I would like to read the
temperature.

=======================================

Haven't come across these ,at least not under this name. I understand they are Power NTC resistors .
Wonder if these would heat-up quickly enough within the 'start-up period' to prevent a current surge.

In the meantime I have tested my Astron RS-50A PSU.
When switched on at 230 V AC (50hz) it sometimes trips the circuit breaker and is rather heavily buzzing ,but when the voltage is increased to that value from zero with a variac the buzzing level is lower .
No-load current is 0.69 Ampere , Power is 28 watts as measured with a multifunction energy monitor.
Having had the unit running no-load for 1 day the buzzing level is acceptable with the transformer being luke warm.

I now intend to include a simple soft start unit (12V relay with 1-2

seconds switch-on delay which shorts a series 50 Ohms-50W resistor (from
junk box) in the primary transformer winding line.

Comments on quality of unit :
-Insulation between primary and secondary winding of transformer looks
rather 'iffy'

- Output connection posts are of the type normally specified for 30
Amperes max.
I shall replace these by more heavy duty posts.

Having done that I intend to test the unit on rated capacity with 4
(approx 1 Ohm) resistors made of iron fencing wire , put in a bucket
with water.

Howdy,

An NTC (or two) should work well in the transformer primary.
It's a common means for reducing inrush at the input of SMPS.
Works fine for linear supplies too. There are numerous
manufacturers of these world wide.
http://www.rti-corp.com/Electronics/surggard.htm

Typical numbers for magnetizing current are 1-5% of the rated load at steady state. And as much as 10-20 times the load current for inrush. I stated 5 times for inrush earlier. It's more than that for commodity (cheaply made) type transformers.

You probably have some load on the transformer, bias power for the regulator, bleeder resistors and so forth. So I'm guessing the idling current is more than the magnetizing current alone. If the transformer is designed for ~1KVA 50A*13.6V times some factor for the regulator efficiency say 0.7 at full load, that's about 970W, then 28W loss at no load isn't unreasonably high assuming the core loss equals the copper loss at full load.

The iffy insulation is a good argument for having the output return of the power supply securely bonded to earth ground.

Fence wire in water should make an excellent load. I've never heard of anyone testing an RS-50 at full load. You might want to sneak up on it. A working 25A supply is better than a dead 50A supply!

It's not just the laminations that make noise. The windings can vibrate if they're not locked in place with transformer varnish or epoxy. No amount of tightening the laminations will help if the windings are free to vibrate. This is probably more likely in larger higher power transformers (multiple kW) than in a filament or screen supply transformer, but it can happen.

Also, depending on how much magnetic leakage your core has you can couple to the steel walls of the cabinetry the transformer is housed in if you don't maintain adequate spacing from the walls, in which case the steel wall and the transformer can vibrate and make noise even though no parts on the transformer are loose.

That's a good point. The filthy leakge inductance will be
spraying its flux all about. But there are things we can
do a to contain it.

A belly band around the winding (but not though the core) helps.
End bells (covers) bolted down over the windows work too.

There may also be fringing flux spewing out of the unavoidable
gaps if it's a butt stack lamination core. Interleaving the
laminations will help.

I've done all of that on a design with the transformer mounted
directly beneath the neck of the CRT in a video terminal.
A requirment of the project manager because he feared
SMPS noise and demanded a linear power supply. Of course
everything had to be jammed into the smallest possible
enclosure and a mu metal shield was deemed too expensive :P

I think something is getting hung during the self-test. It should flash 888 for two seconds at start-up. The sensor is a platinum RTD. Pretty fancy for a soldering iron! Too bad this model has earned a reputation for being unreliable.

There's a "tech sheet" with trouble shooting info but I've never found it online.

We had one of these irons at work and replaced it with a WTCP station.

Don't forget that the inrush current is also going into at least one and
maybe two high capacity electrolytic capacitors that, instantaneously
before initial charging are going to look like zero ohms. Peak current, at
say peak AC volatage when the on switch is turned on, is going to be
higher than you think.

The manufaturers are just too cheap to put any kind of Soft-start
circuitry in to limit this inrush.

  That's not a
> defect though, it's just how things work. The first half

I found several schematics for different models.  Never did find the one
that matches mine.  I opened it up and it seems there is a ceramic board
with surface devices on it.  Almost no user replicable parts.  Atleast for
my skill level.  I was hoping it would be the discrete parts.  I can work
with them.  Oh well, it was free and is a good soldering iron even without
the display.  I do have a couple of spare parts for it also.

I can confirm the 50/60Hz problem. Have been moving line powered equipment (including microwave ovens, Astron P/S, and more - even real Wahl hair clipper) between US/Canada and Europe for over 10 years and found the increased level of buzz when running 60Hz eqpt on 50Hz in practically all cases. My Astron P/S is just a 4A unit and the buzz is bearable. Other stuff ranges from OK to loud like hell.

I finally got around to clamping the transformer down with grade 8, 1/4inch bolts and nuts That didn't help, luckily I found my 3 hour epoxy, ran the transformer for 3 hours straight to heat it up, took the bolts out and with a putty knife slapped on some microwave heated epoxy on the lams. That took the buzz down to below the level of the fan noise. In dead silence you can still hear it. Nowhere can you feel the buzz.

I'm using a Mitsubishi M67749M in my 432 MHz beacon. The only datasheet
I can find at RF Parts shows maximum parameters, etc. There are no
charts showing output power versus such things as Vcc1, Vcc2, Vbb and
input power. Does anyone have the charts for this module?

If you do and can make an educated guess from looking at the various
charts as to what my output power will be?

I have it set up as follows:
Vcc1 = +5V
Vbb = +5V
Vcc2 = +13.6V
RF Input = 20 mW (+13 dBm)

My real question is will I get much output power with only +5V on Vcc1
or should I just tie it to +13.6V just as Vcc2?

THANKS!!

Scott

I used to work for a company (ARCO Oil) that used a bunch of those. Weller closely guarded their schematics and even now they will not release them. We sent them in for repair but they charged about as much as to buy a new one. Here is what I found over fixing a dozen or so.
1) The wire nuts came loose inside
2) Intermittent wires in the cable going to the soldering iron. Flex the cable while ohming end to end.
3) The surface mount electrolytics go bad. These were MOST of the failures and I ended up changing all of them in the rest of the 25 irons we used over about 3 years.
4) The cheap temperature set wire wound pot gets worn out.

Most of the parts in this unit are consumer rated parts and are available. Never had any problems with the ceramic boards in the units or with the printed resistors on them. Had a couple of chips fail. It's an A to D with a seven segment driver built in. They are available still.

Other than the above, they are really a darn good soldering iron and keep the tip temperature regulated fairly closely.

I still have 2 of them so if you decide to throw them away, send them to me and I can use them for parts to keep mine in repair. I will reimburse you for your shipping.

I have more info If you need it.

Rich;
Since the temperature control on mine seems to be working can I assume
the variable pot, the Iron cable and the Iron thermistor are OK? Mine
flashes "EEE" on turn on and then the display goes blank. There are a
number of leaded capacitors on the display board (Mine is actually an
older model 2002-A version). I will try "shotgunning" a;; of the
capacitors with new ones and keep you in mind for the disposal if I buy
a replacement.

Joe: The ones that I have. One board is with the distplays on it has a
couple of regular caps. The other board is ceramic and it had all surface
mount parts. The ceramic board is the one that seems to always give me the
problems. Anyway give it a try.

Thanks. I still haven't had a chance to see if any of these
suggestions fix the problem, but I'll let you know.

The repeater will be used sparingly only during weekends, I don't
think I should have a heat problem. Either way, I do intend on using a
fan.

Thanks!
```

Philippe

Thanks for the reply. I will probably keep the soldering station. It seems to work fine, just no display. Weller made another modle that seemed to be the same unit without the display.   I guess that if Weller did repair them, they probably just changed out the controller board. Similar to what the Commador computer people did. They had a flat repair rate. Don;t recall exectally,but it was something like the board cost them $ 50 and they charged about $ 70 to repair the computer. All they did was throw away the old insides and replace them. Seems this way is cheeper than the labor to repair them.

I would leave Vcc1 and Vbb(bias,I'm assuming?) connected to +5V,to avoid
frying the module.

congrats on the fix..
now you have th epower and the time to contest..
Contesting is much like transformer winding..
Once you learn how to do one turn, you repeat and count until you reach
a goal...
In contesting you do one turn, then another till you reach the time
limit and count your turns.
hi hi

The repeater will be used sparingly only during weekends, I don't
think I should have a heat problem. Either way, I do intend on using a
fan.

We live and we learn.

With Vcc1 at 5V, I get 6.8 Watts out during testing.  It appears I will
actually need to lower Vcc1 just a bit to get down to my desired 4
Watts.  Thanks for the note!

===============================================
 From a list with RF power modules by Mitsubishi I get the following spec :
M67749M
Freq range : 430 - 450 MHz
Po :  7 watts
Gp :  25.4 dB
Pin : 20 mW
Vcc : 12.5 V
Vbb : 5 V      (if a Vbb is indicated ,this is a linear module suitable
for SSB operation )

Vcc (max rating)  : 15 V
Po  (max rating   : 10 Watts

Package outline :  H27

==

On the topic of Weller soldering irons , I would appreciate info on the following :

At a fleamarket I acquired a Weller soldering iron with a DIL16
de-soldering pad (very handy to remove ICs with up to 16 pins.
However , the heater element (Weller part nr 24410 , 24V-50W) is
defective (open circuit)
By Googling I haven't been successful finding a US supplier for the
heater element.
Can someone on this NG please help with US supplier info (in the hope
the cost of a replacement element will not make it necessary for me
having to talk to my bank manager).

TIA for any advice

Frank   GM0CSZ / KN6WH

Hello. I have a homebrew linear 13.8V 20A power supply I have been using for some years to power an IC-735, a 2M rig and some accessories. The PS has these characteristics:

- well filtered (35000uF)22AMP, 21 volt DC output from diode bridge circuit
- LM-317 regulator circuit (as per LM-317 datasheets)
- MJ2955 NPN feeder transistor from regulator driving 4 - 2N3055 PNP power transistors in parallel
- large heat sinks (I don't think heat is a problem)
- good air circulation with fan

I have the regulator set to 13.7 VDC out. Lately however, I have had some problems with voltage drops: while drawing 20 amps the voltage drops to about 11.3 volts and I have had reports of a rough CW signal as a result.

I have tested the reg circuit and even replaced the LM-317 to no avail. I cannot see where the problem lies, unless perhaps the MJ2955 feeder

transistor is not working as it should? (I don't yet have a replacement
transistor to test that idea, hence this post).

Any ideas greatly appreciated.

Larry VE7EA

It's probably not dropping to a constant 11.3V -- it's probably dropping
out on the valleys of the rectifier's output. A steady low voltage
would either render your transceiver inoperable or lower your output
power; the "rough CW" is probably modulated at 120Hz.

Most likely that "well filtered (35000uF)" has turned to "lots of hum
(dried up electrolytics)".

I assume you don't have an oscilloscope. If you do, clip it onto the
power supply output and take a look while you run it close to it's
limit. Any filtering problems should become immediately apparent.

If you don't have fancy equipment just measure the output with your
voltmeter switched to "AC" -- most VOMs will filter out the DC and just
let you see the wiggly part. Do this under both heavy load and light --
if there's a honking big AC component as the voltage sags then there
needs to be some new capacitors in your future.

Hello Frank

Do you have a model number for the iron?  If so, what is it?

In addition to Tim's suggestion, If a rectifer diode opened, you might also experience a similar problem. With a scope, it'll have 60 Hz ripple instead of 120 Hz ripple when loaded.

Howdy,

A few of random suggestions...

The MJ2955 is a PNP and the 2N3055 are NPN.
The pass devices are NPN that make an emitter
follower output which provides current gain.

Load the supply until the voltage drops.
Then measure the base voltage at each 2N3055.
The bases should all be the same, a base to
emitter voltage drop higher than the output
voltage. One of the pass devices may have
failed or the drive current could be insufficient.

I'm guessing without a schematic but the MJ2955 is probably boosting the LM317's output and may also be part of an over current foldback protection circuit. Check the collector voltage it should be nearly the same as the 2N3055 base voltage. If it's much higher that points to a problem with the pass devices. If it's not then there's not enough loop gain.

You may find a high power low value resistor near the MJ2955 for current limiting, check the value of that too. If it's damaged or drifted high you could be hitting the current fold back protection.

The 21V bulk supply will sag if there is a bad rectifier so a check of that under load is a good test. If it's much below 18V that could be too low. The LM317 needs about 3V head room and the 2N3055 will need a Vbe drop.

I think if the bulk cap had dried up you'd hear hum even at lower load current.

You can trouble shoot this with a voltmeter, stage-by-stage, once you load it until it's exhibiting the problem. Once you identify the failing stage a careful visual inspection followed by some resistance and junction checks should solve the puzzle.

73,
Grumpy

Oh!

I forgot to say if the 2N3055's don't have individual base drive resistors, if their bases are all wired together, then you'd have to pull them and check the base-to-emitter and base-to-collector junctions with the VOM to know if one had failed. I've seen a smaller supply built like that and one of two 2N3055 had failed. It made 8A instead of 12A output before going out of regulation.

If there are individual base resistors the 2N3055 with the higher base voltage, because there's no current drawn though its drive resistor, is the bad one.

73,

Grumpy

Hi Ralph,

In my surfing, I found this reverse-engineered service manual for the
EC2002: http://www.geocities.com/bswadener/temp/Weller_EC-2002.pdf or
http://tinyurl.com/5ff6qx (PDF, 372 KB). It may be of use to you and
others.

vy 73,
Bryan WA7PRC

Thanks everyone above for all your input and suggestions. Very useful. I
will get into it and do a few more tests.

Thanks to all that tried to help out.
```

I bought 2 females & now to put one on.
good news is that it now transmits, 60 watts AM & 70 watts out in CW
tune-up.
Now gotta get a decent antenna on it see how it "Hears"\
Tnx all.........

All sortsa info & schematics here on a lot of Adonis Mike's except
your model.
Maybe its a model number which is same as another.
Different numbers for different export ares but same mike, never know!
I have the 308 model as new here so I was interested in your quest to
look around the WWW.
I found this, might be a lead>

Well, The transformer winding doesn separate the way I thoufgt they
did. there is a pretty good sized gap betwen them,1/8" and it seems
one is a choke. I was confused because I have a couple of old scrap
power supplies that are made as previously described. They appeared to
be the same so I made a very incorrect assumption.

Jimmie

Hi Grumpy: Nags me too!!!!!! (OK spot the pun?)

But got to go; to unload my pickup of a free load of firewood got
yesterday (couldn't say no to a second free batch in a week)!

Gee there were two old SPS supplies lying there too; probably all
soaking wet! I didn't even look at the old 14 inch TV lying there as
well in the junk pile.

Wet... well, I wouldn't pass them up!

I've salvaged a few pieces of gear from floods.
My most cherished HP RF sweep generator came out

of the mighty Mississippi river flooding in the
early 90's. First I carefully brush off the gunk
while washing with tap water. Then I flush with
DI or distilled water dry with a fan. Finally flush
with anhydrous isopropanol and dry with gentle warming.
After that a bit of lubriplate on any switch detents
or gears as needed. I take some things out first for
special treatment, like meter movements.

The distilled water flushes off the stuff we worry
about, ionic contamination and the alcohol removes
the water. At least that's what I hope for.

I'm trying to reform and not drag so much junk home.
Sometimes I can even pass up junked hardware without
flinching. With technical books of any sort I'm not
having much success resisting though.

Mmm! Free firewood. Which reminds me, I need to fill the
wood shed yet. Oak wilt disease is killing my trees but
at least I'll be warm.

About 6 years ago while hauling off some junk from my in-laws home near Jacksonsonville Fl some stuff caught my eye at the dump. There were 3 tektronics scopes, a singer communications monitor and an audio test set. All worked and some of the pieces had current calibratiton stickers. Up until then I had been grumbling alot about wasting days of my vaction time cleaning.

Jimmie

COMPUTERS - ELECTRONICS - HAM RADIO - COMPUTERS - ELECTRONICS - HAM RADIO

FLEA all SUMMER at MIT
Sunday October 19th 2008
9AM-2PM

Come to the city for a great flea - plenty of free parking.

MIT's electronics and ham radio flea will take
place on the third Sunday of each month this summer,
April thru October.

There is tailgate space for over 600 sellers and
free, off-street parking for >2000 cars!

Buyers admission is $5 (you get $1 off if
you're lucky enough to have a copy of our ad)
and sellers spaces are $20 for the first and
$15 for each additional at the gate.

The flea will be held on Albany between Mass Ave and
Main streets in Cambridge; right in the Kendall
Square area from 9AM to 2PM, with sellers set-up

time starting at 7AM.

*** Attention Sellers ***
Prepaid vendors.. Season Pass or monthly,
will be admitted FIRST.
Separate lines will form prior to gate opening
for prepaid and nonprepaid vendors

!! RAIN or SHINE !! Have no fear of rain, a covered well illuminated tailgate area is available for all sellers (6'8" clearance).

Talk-in: 145.23- (PL 88.5) W1BOS/R and
W1XM/R-449.725/444.725 (PL 114.8/2A).

Sponsors: MIT Electronics Research Society
MIT UHF Repeater Association (W1XM)
MIT Radio Society (W1MX)
Harvard Wireless Club (W1AF)

For more info / advanced reservations 617 253 3776 (M-F 9-5)

********** $1 buyers discount with hard copy of this notice ************

Hello.

I have a IC-R2500, and I'm trying to establish a link between the
radio and my computer.Does anyone know the standard that dictates the
RS-232 packets that are sent between the radio and the computer?

Also...I've seen that the most common approach is communicating over a
CT-17 cable (1/8 stereo to 9pin female serial). Does anyone know
if this is connection is straight through, or is there some sort of
voltage shift?

Thanks
nathan-fritze@engineering.uiowa.edu

I was considering the purchase of a Hazer until I read the numerous
down reveiws with quality, service, documentation and jamming
incidents too numerous to mention.

Anyway, there was mention of plans out in the ham fraternity for
homebrewing an improved reliable version, so was wondering if anyone
could steer me in the right direction? I'm not too good at web
searching.

They had a second scheme that consisted of a frame that traveled up the legs of one face of the tower on rails. I don't think they ever sold any, but it looks like an alternative that could be homebrewed.

I used to know  some guys that built  a few while serving as
full time techs for the national guard. They bought one and then
copied
it making improvements mostly in the form of better quality parts.
Fortunately for them that had access to some pretty decent equipment,
welders, lathes, drill presses, nearly unlimited parts resources. My
contribution to the project was designing a thrust bearing that would
survive a salt marsh environment. When I was asked for an idea on it I
had just overhauled a motorcycle clutch so I thought OK use the same
idea for the clutch but instead of using something that has a lot of
friction use something really slick between metal plates. This took
the form of three or four stainless steel plates separated by sheets
of Teflon. Its my understanding that these devices survived the next
eight years with zero maintenance there use terminated only because
they were no longer required.

Hello Joe;

Thanks for the tip, I do remember the rail system now that you mention it. It seems a more doable project, less complicated and would make positive contact with the rails rather than haphazard like mentioned in all the reviews and user comments.

One of the thoughts I have had on building a Hazer is to slide a piece
of 45G tower section over my 25G tower. I guess I will have to buy a
short tower section to see if this is plausable. Im sure guides and
roller additions will be required but this may be a good place to
start a design. This is something I will probably try at my next home
as for now am I still able to climb.

Jimmie

However, John McCain's actual behavior from October to December 1967 is quite different from the Navy's version of events.

On October 27, 1967, four days after being shot down, McCain called for a North Vietnamese guard. He told the officer, "O.K., I'll give you military information if you will take me to the hospital." -U.S. News and World Report, May 14, 1973 article written by former POW John McCain

McCain was taken to Gai Lam military hospital. (U.S. government documents) "Demands for military information were accompanied by threats to terminate my medical treatment if I [McCain] did not cooperate. Eventually, I gave them my ship's name and squadron number, and confirmed that my target had been the power plant." Page 193-194, Faith of My Fathers by John McCain

On Nov. 9, 1967, Hanoi press began quoting the seriously injured McCain giving specific military information.

One report dated read, "To a question of the correspondent, McCain answered: 'My assignment to the Oriskany, I told myself, was due to serious losses in pilots, which were sustained by this aircraft carrier (due to its raids on the North Vietnam territory - VNA) and which necessitated replacements.

"'From 10 to 12 pilots were transferred like me from the Forrestal to the Oriskany.

"'Before I was shot down, we had made several sorties. Altogether, I made about 23 flights over North Vietnam.'"

In that report, McCain was quoted describing the number of aircraft in his flight, information about rescue ships, and the order of which his attack was supposed to take place.

Through the Freedom of Information Act, the U.S. Veteran Dispatch acquired a declassified Department of Defense (DOD) transcript of an interview prominent French television reporter Francois Chalais had with McCain.

Chalais told of his private interview with POW McCain in a series titled Life in Hanoi, which was aired in Europe. In the series, Chalais said his meeting with McCain was "a meeting which will leave its mark on my life."

"My meeting with John Sidney McCain was certainly one of those meetings which will affect me most profoundly for the rest of my life.
I had asked the North Vietnamese authorities to allow me to personally
interrogate an American prisoner. They authorized me to do so.

"When night fell, they took me---without any precautions or mystery--to a hospital near the Gia Lam airport reserved for the military. (passage omitted) The officer who receives me begins: I ask you not to
ask any questions of political nature. If this man replies in a way unfavorable to us, they will not hesitate to speak of 'brainwashing' and conclude that we threatened him.

"'This John Sidney McCain is not an ordinary prisoner. His father is none other than Admiral Edmond John McCain, commander in chief of U.S.
naval forces in Europe. (passage omitted)'"

". . . Many visitors came to talk to me [John McCain]. Not all of it was for interrogation. Once a famous North Vietnamese writer-an old man with a Ho Chi Minh beard-came to my room, wanting to know all about Ernest Hemingway . . . Others came to find out about life in the
United States.

"They figured because my father had such high military rank that I was
of the royalty or governing circle . . . One of the men who came to see me, whose picture I recognized later, was Gen. Vo Nguyen Giap, the
hero of Dienbienphu." U.S. News and World Report, May 14, 1973 article
written by former POW John McCain

December 1967, Vietnamese doctors operate (early December) on McCain's Leg. Later that month, six weeks after he was shot down, McCain was taken from the hospital and delivered to Room No. 11 of "The Plantation" into the hands of two other U.S. POWs, Air Force majors George "Bud" Day and Norris Overly. They helped further nurse him along until he was eventually able to walk by himself. --Faith of My Fathers by John McCain

Read retired Army Col. David Hackworth's opinion of Sen. McCain's medals.

STAY TUNED, MORE OF MCCAIN'S CITATIONS WILL BE POSTED HERE SOON

```

The EA53 detector in my HP410C finally went bad. I was hoping someone knew where I could find one at a cheap price or maybe replacement circuit. The last time it went bad I paid over $100 to replace it and it still looks like thats about what they go for now. I only occasioally use it for work over 150Mhz so if a less expensive detector or probe could be had I would be interested even if it was frequency limited compared to the 410.

Thanks much

Jimmie

Hello All

We have a propagation issue that is confusing us. We have two 868MHz modules on test, each capable of 500mW transmission.

We are testing to find the range of communication. We are testing them as follows. One remains in our office while the other is taken to the street outside. we are communicating charecter strings such as "Im at the lamp post number 1" etc. There is somebody at each end sending text strings in a continuous conversation. There is no protocol, error checking or error recovery.

What we have repetadly found is that the radio in the office can receive long after the radio in the street has stopped receiving. (The person with the radio in the street is moving away from the office.)

The radios are the same and the power supplies to the radios are the same. Indeed switching the radios gives the same effect.

The propagation paths between the two radios are the same in terms of distance. However the radio signal transmitted from the office travels through walls first before then traveling through open space. Its the opposite for the radio in the street, firstly traveling through space and then through the walls in the office.

We did think we had identified an interfeering source in one direction (when moving away from the office) so we started moving in the opposite direction. We found exactly the same effect.

Are we getting interfeerance from GSM, ISM or Paging?

As far as GSM bands go in Europe 890=96915 MHz OR 1710=961785 MHz So these shouldnt be our problem.

ISM is where we intend to operate and the greatest band occupancy should be 10%. So we should get communication even though we would get some interfeerance.

Paging - well this has very much gone out of fashion in Europe. But even if it was the cause then wouldnt it be intermittant communication. We have a constant problem.

Can anyone shed light on this phenomonon? Is it an issue of wireless propagation that Im not familiar with or is it Interfeerance?

Best regards, and thanks for any input.

Denis

You may experience receiver desensitization from a strong out-of-band
interferer which is not penetrating well into your office and hence not
interferring there.

Pere

Hi Guys

Thanks for your input on this.

The idea of height being a problem is interesting. The radio in the
office is on the 1st floor (i.e above the ground by one floor).

If the antenna were at the same height would the problem go away?

We will test and see

higher antennas = longer range. Thats your issue.
Also lack of error correction, poor antenna pattern to meet the low
power regulations, and a less then robust protocol, ie your probably
using some form of on/off modulation where the receiver does not have
a continious wave signal to locl on and track. Try sending a preamble
character that is 10101010 a few times, assuming your receiver is

sophisticated enough to use AGC. This sets the DC level in the discriminator more accurately and reduces errors.

your using a radio with intentionally designed in limited range to allow reuse of the frquency.

Steve

news:159dee31-5436-4f46-ae9d-48214eec09ca@k37g2000hsf.googlegroups.com...

What we have repetadly found is that the radio in the office can
receive long after the radio in the street has stopped receiving. (The
person with the radio in the street is moving away from the office.)

The radios are the same and the power supplies to the radios are the
same. Indeed switching the radios gives the same effect.

Is your office in a concrete building? Or one with any steel reinforcement
or steel or aluminum studs? If so, it could well be that there is a
standing wave issue, so that a portion of your transmitted signal is being
reflected back, and so not making it to the receiver. This would not
necessarily affect the reception on the radio in the office from the outside
radio.

The radio outside is likely being desensitized by some other signal.

I see you have other responses. One test that would establish that is environmental (adjacent signal, receiver desense, etc), if BOTH units could be moved to a relative RF free environment such as a rural setting and then test the range.

If this eliminates the problem, then its probably time to break out a spectrum analyzer and take a look at what is around your operating frequency.

Andy

It's because the paths are not the same. Think of a silvered mirror. It can transmit light much easier in one direction than the other. Take both outside and see if it has the same problem. (extremely doubtful because the path's is virtually identical)

Did you design the receive software?
Or did buy the receiver "off the shelve"?

Perhaps there is a problem
with the receivers and how they are
receiving the data.

Did you design the receive software?
Or did buy the receiver "off the shelve"?

Perhaps there is a problem
with the receivers and how they are
receiving the data.

um, did you read his message? He said that it was independent of the
receiver because they exchanged them and the same problem. i.e., it helps to
read the original post.

>What we have repetadly found is that the radio in the office can
receive long after the radio in the street has stopped receiving. (The
person with the radio in the street is moving away from the office.)

You don't say if you are using the same antenna on both ends, but the environment is very different at each end. Consider that Transmitting is about putting signal into an area, while receiving is about capturing the signals in near field of the antenna, then discerning the intellegence. You would have to analyze the output to be sure, but it may be localized reflections, shading or noise at the street level. Because of this it is so difficult to quantify range. There is equipment and software specifically designed to do what you are trying to do but it is expensive. The result is highly detailed signal strength graphic output overlaid on 3d mapping for each fixed site at various frequencies. Most commercial antenna sites have gone to great expense to generate those maps in order to show what their tower does because it is very different for each location.

Is the moving station manually portable or is it mounted on a vehicle?

If the moving operator is bored and continuously talks on a GSM phone
or if the (vehicle) generates some other kind of interference, this
would reduce the SNR at the moving station.

Does the transmitter have some kind of SWR protection ?

If the Tx antenna is close to the wall, it might detune the antenna,
increasing the SWR and the SWR protection drops the transmitter power.

Such as traffic light electronics.

Without error correction protocols being employed, you are also at the mercy of multipath interference. You're QRMing your own signal. 8>)

Polarization could be a factor.
Reflections change the polarization appr. 90 degrees.

Rotate the antennas left & right to find out.

(you did not mention your type of antennas)

Have you tried relocating the office transceiver? There might be
something about the office environment that is interfering with its
transmission.

wow so many of these replies are wrong..

in almost all cases, RF path losses are RECIPROCAL.

(even a 1/2 silvered mirror is reciprocal to light)

As some have said, the cause of your issue is probably interference to
the outside receiver.

Or maybe something about the indoor setup is causing the indoor Tx to
operate at lower power.

It is very unusual for RF path loss to be non-reciprocal.

Mark

If I remember my antenna/propagation theory correctly, such a change should affect both the transmit and receive gains equally. That is to say, if moving the office antenna lower will reduce its transmit range, it will also reduce its receive range.

What you are looking for is something that is reducing the office end transmit power while leaving its receive sensitivity intact. Someone else suggested an SWR problem due to near field interference with the antenna.

Most likely scenario.

Also make sure that in your design you are powering down the transmitter
fully in the receive mode. In some radios there can be a residual
carrier from the PLL causing self interference ar interference to other
nearby nodes.

That's what I think is the most likely cause. The guy outside probably has his Nextel phone with him. ;-)

I suppose that's possible too. The OP should make sure the power supplies are equivalent (meaning that the output power would suffer more than the receiver gain with a drooping supply). So check the indoor supply.

It is assumed that the path to and from the office should be inferior
to the line of sight path out on the street. This may or may not be
true. The building may actually be offering gain in certain
directions. I would start by seeing if the same condition existed at
many more locations. If it does then other ideas need to be examined,
I would start by examining the RF environment outside the building.

Jimmie

Hi Denis,

That is a lot of power for a problem of losing contact in the space of
blocks.

>What we have repetadly found is that the radio in the office can

A very good description of the symptoms and relations.

>We did think we had identified an interfeering source in one direction
>(when moving away from the office) so we started moving in the
>opposite direction. We found exactly the same effect.

A good test for reducing variables. If you identified an interference, I would presume you could do that again in the other direction.

>Are we getting interfeerance from GSM, ISM or Paging?

Only if the remote set was nearer to an undiscovered interferer. You seemed to have resolved that once, and you should be able to detect the similar occurrence again.

>As far as GSM bands go in Europe 890�915 MHz OR 1710�1785 MHz So these
>shouldnt be our problem.

This is a flaw in the logic. Your frequency of operation is very close to these bands - unless your sets have been designed with elaborate front end tuning (which seems unlikely).

>Can anyone shed light on this phenomonon? Is it an issue of wireless
>propagation that Im not familiar with or is it Interfeerance?

One component not discussed is the remote set's proximity to the operator. The operator could disturb the local field (aka shield). Going beyond is the effect of a Fresnel Zone, but your descriptions describe a complete black-out. To test this requires you to go further away to see if you pick up the signal again. This is a long shot, however, as the effect would be distinct within the space of a meter or so. For mobile operation, the Fresnel Zone creates what is called "Picket Fencing" as the signal comes and goes quickly with distance traveled.

Perhaps it is the proximity of a Pub, and your operator stopped in for a Guinness.

I'll second Pere and Anthony. Strong out-of-band signals is what I found mostly in situations where path losses seemed strangely non-reciprocal.

Post a schematic. One possibility is that your receive input filter is wide open like a barn door and GSM swamps the receiver.

Another option if you have a spectrum analyzer: Hang a large near-field probe into a long cable, tape it to a broomstick and hold that out the window for a while. See what pops up on the screen. If this is in a city be prepared for some commotion among the pedestrians down there :-)

Hey:

My crystal balls are saying:

Multipath where a reflected signal from the source is being cancelled out in the zone sort of like standing waves. It's like waves in a bath tub they bounce of the sides and produce more interference waves, and so on. Or FM broadcast stations signal in the big city with tall buildings, all of a sudden the signal just goes puff while you're driving along downtown.

I'd say gits your antenna near a window or put up an outdoor antenna.

Reading QST at B&N is not "sampling". It is hypocritical. Since you are boycotting the ARRL by not being a member, your "sampling" of the magazine in the book store is absolute hypocrisy. You want the benefits of the organization without paying for them. If you are going to boycott the ARRL, do it right. Don't read their magazine.

Understand that inside a typical computer switching power supply there is a higher multi kilohertz voltage (350v RMS????) produced by the switching action of the rectified 115 or 230 volt AC input?

This high freq AC through various usually toroidal step down transforner windings is then rectified to provided the plus and minus 5, 12 volt outputs etc. Correct?

We recently modified such a power supply to get a single 12 volt DC output at about 20 amps for a particular, amateur radio application. In order to do so we had to load one of the 5 volt ouputs with a couple of amps in order to get the unit to work; but that's normal.

Question: Is it possible to get at that higher AC voltage inside and directly rectify it as a B+ supply for tube equipment? While also possibly tiddling one or more of the 5 volt DC outputs closer to 6.3 volts for tube heaters?

Rectified 10 or 20 kilohertz wouldn't need much filtering compared to 60 or 120 DC ripple of a conventiaonl power supply? Recall building a number of conventional 50 and 60 hertz power supplies many years ago with heavy chokes and large capacitors. But now have a number of slightly older ex computer power supplies of various wattages around.

Or is the idea completly off base?

It is a Psychological defense mechanism to go to great extremes to construct a justification for doing something we deep down feel is wrong. We lie to convince ourselves they have done some great wrong, and we lie to ourselves that we never do wrong to anyone else.

Somehow this has become the norm, but that doesn't mean it isn't anti-social or even destructive behavior.

"Do unto others as you would have them do to you" (and don't fool yourself into believing you really are).

Of course I would prefer no one used ME as a training example, so perhaps I am guilty too. Perhaps if I don't give the person's name I can forgive myself?

You're pretty much on base with some some slight adjustments.

The switching frequency is about ten times higher about 100KHz or so. The high voltage might be full wave rectified, doubled or boosted by a power factor corrector ... but 300V is close.

The step down transformer is usually an E-E core or ETD core. The toroids are output inductors. An additional inductor is used for 3.3V in some supplies as a magnetic amplifier, which lops off some pulse width from the +5V output.

It's possible to modify a PC supply and add a B+ output but you'd have to re-wind the transformer and output inductor(s).

Usually the outputs are cross-regulated. That is the +5V is the regulated channel and the other outputs track due to the transformer turns ratios (sometimes with help from weighted-sum voltage sensing.) That's why the 5V output has to be loaded to get any output from the +12V.

If the 6.3VDC output was most of the power it would make sense to use the 5V channel for this, strip off the other outputs and wind a new secondary for your B+ in their place.

You're right, the transformer and filter components would be much, much smaller. Though you'll need room for additional EMI filtering... even so it's still much smaller. Some newer PC supplies spread the clock frequency (frequency modulate it with pseudo random noise) which can help.

Savvy Competitor Analysis and Keyword Research Your Competitors Arent Doing

By Dave Davies - Wed, 10/01/2008 - 5:12pm.
First, let=92s tackle competitive analysis. As an entrepreneur, you're no doubt familiar with some of the conventional wisdom about how to handle competitors. Do your research. Check public records and disclosures about big name firms in your industry. Assess your goals, branding plans, and future efforts in the context of the presumptive goals of your industry rivals. Understand why customers choose competitors over your firm -- both why they like your rivals and why they refuse to work with you.

Beyond this broad and relatively intuitive theorizing about competitor analysis, however, you may not be that up-to-speed on the latest tactics.

First of all, purchase stock in rival companies. This may seem counterintuitive =96 why support a rival firm at all? - but great benefits await. Stockholders get regular reports on firms=92 finances and long-term strategies. You can glean a lot about your rivals=92 positioning -- and see what other stockholders are saying -- all without wasting dozens of hours on frustrating Internet research.

Second, learn from your competitors=92 competitors. You may have heard the expression =93my enemy=92s enemy is my friend.=94 This tactic makes use of a similar concept. You don=92t have to do all the =93oppo=94 research yourself -- you can trade ideas, data, and strategies with mutual competitors. Learn your rivals=92 weaknesses as well their strengths. The devil you know is almost always easier to handle than the devil you don=92t.

Stay up-to-date on what=92s happening in your industry. Go to conferences. Don=92t delegate the responsibility of watching your rivals to a third party. Attend trade shows. Use Google, the Internet, and public archives to investigate competitors. Don=92t let your guard down -- even if you are an established =93big dog=94 in your field. Be knowledgeable and networked, and you will be less likely to be surprised.

Finally, remember that the competitive landscape is always fluid. Your biggest competitor next quarter may be an unknown today. Given the advent of global business markets and the mixing of industries that globalization has created, there is almost no way to anticipate what =93the next big thing=94 will be in your industry. But simply by maintaining a flexible posture, you will be more agile when responding to new challenges.

In terms of keyword research strategies that defy the conventional wisdom, your best bet in general is to try out a variety of tactics in a microcosm and then apply the ones that work in larger =93marketing laboratories.=94

Employ abbreviations, acronyms, and shortcuts -- real shortcuts that people searching on Google would actually use. Keep things simple:

=93personal computer=94 might be abbreviated as =93PC=94; the month of =93January=94 may be abbreviated as =93Jan=94; and so on.

Zero in on better keywords. For instance, if you are marketing a Phoenix real estate site, you might want to have a keyword for =93Phoenix AZ real estate,=94 since many people who search Google will abbreviate Arizona as =93AZ.=94

Anticipate typos, malapropisms, and misspellings when coming up with your keywords. People may type too many or too few letters in a word, omit key vowels, or switch letter orders around by accident. There is a great site -- searchspell.com -- that can help you guess the most popular misspellings and typos for particular words and phrases.

Throw geographical references into your keywords. The more specific your geo targeting, the easier time you will have not only at attracting local business but also at ranking high in the general =93lottery=94 for Google rankings. For instance, if you are advertising a Connecticut law firm, don=92t just create keywords based on permutations of =93Connecticut,=94 =93CT,=94 =93law,=94 =93lawyer,=94 etc. Throw in name=s of nearby towns that your office would service, such as =93Simsbury,=94 =93Avon,=94 =93Farmington,=94 =93Bloomfield,=94 and =93Hartford.=94 You will have an ea=sier time ranking, and your resultant visitors will feel you are speaking and relating more specifically to them.

To increase the effectiveness and conversion of your keywords, think about the action your demographic needs to take and titrate your keywords down to specific action-oriented phrases. =93Los Angeles mortgages=94 has some measure of geographic filtering; =93Los Angeles mortgage brokers=94 is better and more specific. But =93Los Angeles home mortgage application=94 is better by leaps and bounds because the phrase carries a significant amount of implied intent. Of course fewer people will search using that term, but the ones that do are further along in the cycle, closer to closing a deal, and ready to take action.

We at Beanstalk use AdGooroo's keyword tool and competitor analysis services to get an even more in-depth look at what our competitors are doing online to make sure we're not missing anything. In this whole article =96 it's probably the more recommended of the tools.

Finally, consider these all-purpose tips when piecing together your keywords and key phrases: liberally employ descriptive adjectives (=93top=94 and =93free=94); vary up your verbs; use both singular and plur=al permutations of critical words; rank for domain names if and when appropriate; and research what your closest industry rivals do and plot out your marketing strategy at cross purposes, as well as on a parallel track, and see what true independent, even contrarian thinking can do for an enterprise. The bottom line, of course, is persistence and determination. You can get help, like this article, to work smarter. Working harder, of course, is up to you.

The "higher voltage" is usually on the line side of the isolation transformer. You would create a safety hazard by accessing that voltage.

A thought might be to use the non-rectified low voltage side to drive a small high frequency step up transformer or use a diode voltage multiplier circuit or a combination of transformer and voltage multiplier.

There is a company that builds high voltage switchers for amateur radio amplifiers, and there have been construction articles to build these. (Check QEX magazine).

Building from a surplus PC power supply would have a cost advantage.

There's a schematic of a typical (although a bit dated) ATX power supply that shows the concept of a PC power supply design at http://www.pavouk.org/hw/en_atxps.html. Current models might use different components but the basic design will be the same.
Here, you can easily see the building blocks of the supply and how the various voltages are generated.
There's also a link on that page (http://www.webx.dk/oz2cpu/radios/psu-pc1.htm) that demonstrates a way to modify a power supply for high current +13.8V output.

Modification for HV output would obviously involve rewinding the switching transformer to give it a HV winding.

Regrettably the author of the key article, and owner of the company "Watts Unlimited", died a few years ago.

The commercial unit followed some years after the QEX article. It contained a number of important improvements but schematics were never published. The big unanswered question is why that design had no voltage feedback, and therefore had quite poor output regulation? (We can only speculate that a feedback loop must surely have been tried, but proved unworkable... and then wonder why that should be?)

An example application for the commercial unit:
http://www.gare.co.uk/k5and/8877.htm

>Building from a surplus PC power supply would have a cost advantage.
>

These days, tube RF amplifiers only begin to show a clear advantage over solid-state at 500-1000W RF output, ie 1-2kW DC input. That is way beyond the capabilities of PC power supplies.

A small-scale project based on a PC supply would be a good way to begin to understand the problems, at relatively little cost, but it would be another big step to build (or modify) a much larger SMPS for a serious tube amplifier.

Pshaw

I used to make a living fixing TV sets that ran off of the mains wit
no isolation. Needless to say there were millions of these TV's back
in the day, The trick was to use half wave rectification.
You can do the same thing with a PC supply. Instead of using an AC
input you would half wave rectify the AC and and a suitible filter
capacitor to make up for the frequency change. Also you has to use the
neutral as ground, and use a polarized plug in the USA, Now it's true
if the wall outlet got wired the wrong way you could be in for a treat
of epic proportions. So a GFI would be in there somewheres to protect
you. Then your HV DC ground will be at neutral. At which point you
could use a Voltage multiplier to get close to any whole number
multiple of the mains voltage.

Now it's true you you may not get away with this trick on 3 phase or
split phase 220 mains, because then where is the neutral?

Hey terry

I did that very same thing loaded the 5volt with 5ohm at 5 watt.
Ran my TenTec 526 off the 12 volt side of the PC power supply.
I thought it was the sweetest thing since sliced bread. Then
people started telling me I had this strange background noise.
They asked me what was going on in my shack. I had this strange
eerie noise in my shack, so they thought. Wasn't in my shack per
say but it was the PC power supply. Nobody knew I was running
a PC supply to power my rig.

I also use a modified PC power supply with no problems. I did add a
filter removed
from a commercial computer SMPS. I dont know the values of the
components but its a Pi filter
and the inductor is wound on what looks like a ferrite rod. The caps
are some pretty big disk

that had the writing rubbed off of them a long time ago. As Grumpy put it. I like to "Frankenstien" some of my projects.

I have been giving some thought as to what it would take to modify a PC power supply for HV use.
I have been thinking along two lines,

1 Connect a second step-up transformer before the rectifiers.
2 Replace the transformer with one with a HV windingputting a 5volt winding on the new transformer for loading and feedback.

Joel -
  In fact the BFO for your radio is already in the IF bandwidth, and
there probably is some leakage into the IF amp.

  For most applications, you don't notice that leakage unless you
wonder why your AGC is kicking in but you aren't hearing anything.

  I have found that keeping the BFO out of the IF, especially for a
diode-mixer-level BFO (+7dBm) requires putting the BFO in a box.

  I would expect that putting your DDS in a box will help in general.

Tim.

I was thinking of several layers of milled-from-billet cabinets between
the signal and the receiver.  I suppose I should have mentioned just
what I meant by "enough".

Surely it's easier to take the circuit; wrap it in kapton tape, hold it by the
output leads, and dip the entire thing into molten lead? :-)

Guten Tag Radio Aficionados!

Great opportunity to get out and have some fun with ham friends. The special
```

table is reserved for those wearing their callsign hat or badge. Come and celebrate Yuri's 50 years in ham radio and check out this site for future Ham radio conventions the MountainView Resort in Glen Spey, NY.

As you may know, the Ardmore Mansion has been elegantly renovated this past year. Our motel units are currently being refurbished and the Black Sea Ballroom and Brew Pub are beaming with restored wood floors and new interiors. Our new pavilion is almost finished and will be ready for large outdoor events.

We are gearing up now for Oktoberfest, which will be held on Columbus Day weekend, October 11-12, bigger and better than ever. We will be featuring authentic German food and specialty Oktoberfest German beer, vendors, and games for adults and kids alike! The highlight of the evening is Jagermeister's own Fritz's Polka Band, performing live at the Saturday night dance. Also, for two nights only, Dark Forest, the area's premier Halloween events company, is presenting a Haunted House at neighboring Burn Brea Mansion. They will be celebrating the mansion's 100th anniversary by charging the same rates ($10 per person) they charged the last time the show was presented, 10 years ago! Transportation to and from Mountain View will be provided at no additional charge.

On Friday night, October 31, we are hosting a Halloween Masquerade Ball, with costume contests, dancing, and a frightfully fun time for all! Ages 21 and over, please. Then, on Saturday November 1, we present our Fall Festival & Market. Come and sample the best of the area, and enjoy the leaves changing colors while sipping on Mountain View's specialty cider.

Please check the web site for the latest news and programs at www.MVresort.com and check out or download the posters for more information. Spread the news, bring a friend and see the progress at MountainView. We are building our mailing lists and soon will have regular newsletters informing our patrons about the latest and upcoming events at the resort. Please pass on email or postal addresses so we can stay in touch.

See you at MountainView!

Yuri and the crew
please email me if you are coming
K3BU@optimum.net

Great info: Thanks for all the ideas and especially about the warning that the HV would be on the line side (input) from115/230 volt mains. Unless a 60 hertz full isolation transformer were used; the weight and size of which sort of negates the idea of using a lighter weight SPS!

I too used to fix TVs without power transformers, using selenium rectifiers (boy could they stink!) and voltage doubler circuits to provide B+. That was back in the mid late 1950s. I also made up a little B+ power supply in a box clipped in during house calls to show a customer that the problem was indeed inside the chassis and it had to be taken away for a 'bench job'!

By that and means of never charging for a house call if I didn't fix the set in situ; built up a reputation for straightforward dealing which, despite the slightly funny accent of a British immigrant to Canada, some 15 years later, may have helped me become elected to the areas first town council? And that in a day and age when TV repairmen didn't have the best reputation in the world (well at least around here) for ethical dealings!

These days customers are a lot more cynical and questioning; and rightly so!

BTW first heard about SPS in the telephone industry, before PC were common; when power supplier representatives started telling us about 'rectifier/power supplies' that had efficiencies of over 80%.

That's right. We're radio amateurs. I forgot...

What flux makes lead stick to Kapton?

(snip)

I worked on a 13.8 Volt SMPS made by TODD for Motorola as an OEM without
any documentation. There was a large stud mounted 13.8 Volt zener on the
output to clamp the voltage and some op amp circuitry to sense if the
output voltage fell below 13.8V it would start increasing the PWM to
charge the filter caps. This PS apparently never worked right because
the transformer leads were never soldered and then were plastered in
conformal coating.

Sure it is the correct term, but when the manufacture call it a duplexer,
that is what you look for. They are even listed that way in most ham
catalogs. I doubt that you will find a diplexer listed in the ham catalogs.

The AES catalog lists Comet,Diamond , and MFJ duplexers and triplexers, but
not a single diplexer is listed.

I know it's possible to do a modifiction to have the squelch working in all modes with a Kenwood TS-14S.
I would like to know if some of you have already made this mod and if it really works.

Thank you in advance,

T0M

The 300 volts you wanted is on the input side of the power supply, not
what you wanted. This does not mean that the output of the power
supply is not isolated from the mains. The type of switching power
supply you wanted is probably doable. Think about removing the output
transformer from a PC power supply and connecting it back to back with
the transformer in a working power supply. The output could be
rectified and filtered and you would have a cheap to free lightweight
line isolated HV power supply. I am in thr process of trying this. I
not getting much work done on it due to my present work schedule but
in a few weeks things should get back to normal and I will have a
chance to play with my toys some more.

I am just getting in to SMPSs and find it amazing what these things
willl do.
For example I found a a +- 15 volt unit that puts out 100 amps for
each voltage. I can hold the output transformers in my hand, they
couldnt weigh more than a pound each.

Jimmie

You might find this useful Jimmie.

I had some time to cobble together a DC-DC "transformer" this weekend. It is a half-bridge running at 200KHz and fixed 96% duty cycle. The turns ratio is 1:24 and the output is full wave rectified. I'm using an EDT29 core, I think the material is 3C90.

The rectified AC line was ~160V and the output was ~1800V (I'm using a Simpson 260 so the voltages are thereabout.)

After running 300 watts though it for two hours the transformer wasn't near warm. If I take this further I need to build a real load.
A bucket of distilled water and some magnesium sulfate (epsom salt) isn't stable when it's boiling.

It's a small transformer and light. It's not regulated but I think it could replace a much larger laminated steel transformer.

Takes a rainy day for me to find any motivation for stuff like this.
Maybe after winter arrives I'll build it up properly and try it in the SB200.

Grumpy , when David Smith was testing out the uwave oven power supply
he use a big russian made triode as a dummy load.
Forgot the #, GS 35B or something like that. I was going to get one,
use it for a dummy load now and later build an amp if I dont blow it
up.
Jimmie

Posting-Frequency: posted monthly
URL: http://www.faqs.org/faqs/radio/personal-intro/

Changes followed by "|".

The rec.radio.info newsgroup, first established in 1993, has been recently revived by an active moderation team. We are currently seeking suitable information, FAQ, and bulletin articles from the entire rec.radio.* newsgroup hierarchy for simultaneous cross-posting to our newsgroup.

We are seeking a replacement maintainer for the following information bulletin formerly posted to rec.radio.amateur.* (and currently archived at http://www.faqs.org/faqs/radio/personal-intro/):

```
 radio/personal-intro
 Subject: Guide to the rec.radio Newsgroups
 Maintainer: jeffreyh@Hawaii.Edu (Jeffrey Herman)
 Last Posted: 9 Nov 2001 06:18:17 GMT
 Posting-Frequency: 15th of each month
```

We are willing to provide any technical support necessary to get this article updated and automatically posted again at a regular interval. This would include establishing contact with the original maintainer for any necessary permissions. We would prefer to seek a new, dedicated maintainer at this time, rather than start auto-posting the original article ourselves.

For more information about our newsgroup, see:

http://www.panix.com/~rram/usenet/rri/index.html

Please direct any comments, questions, or criticisms to rec-radio-info-request@panix.com.

So I'm not sure what the question really is here. Do you want to charge a capacitor faster, or get some small vehicle to run faster over a particular course?

You can't escape physics: to charge a given capacitance more quickly, feed it more current. If the source of energy for charging it is greatest at a particular voltage (typical of a photovoltaic array), use an efficient converter to go from that voltage to the highest current you can achieve at the instantaneous capacitor voltage.

You can't escape physics: if you want a vehicle to traverse a path in the least time on a given amount of energy, reduce the losses (e.g. friction and air resistance) to a minimum. As a second-order effect, consider how inertia affects the speed too.

Though you can put some practical bounds on how well you should expect to be able to do, there are certainly many ways to arrive at a solution. Engineering solutions like this practically always involves compromises and tradeoffs. You get to decide how to best accomplish what you want to do, always under some constraints that generally include both explicit and implicit ones. Math is one of the tools you can use to optimize your solution: consider the equations for motion and loss of energy; consider the equations for conversion of energy from one form to another.

Cheers,
Tom

A resistor in series is the simplest way.

You can slow charge while powering a light load, then short the resistor
into the load for a burst of current for a high load, but if that's not
enough, will you still have enough to charge the capacitor AND power a
medium load.

It won't get you up a hill, but it might be enough to get you rolling.
Gearing change might be more versatile for the same weight

I had a little time yesterday and opened up a PC power supply and
brought the 3 taps off of the transformer out to binding post. The
plan is to build a transformer that will step the voltage back up to
about 800 volts or so, enough for my little 6146B 6M amp.

Jimmie.

Like you said I like to Frankenstien things. I have a filter from
```

another power supply but I am not sure how well it will work as it was designed for about 25 amps. Basically thats a bridge I will jump off of when I come to it. Right now I am having enough trouble finding an old PC power supply I can get a transformer from. Its hard to believe about a couple of months ago I tossed about a dozen of them. Last time I listen to my wife. I do have a couple of transformers from some old Lambda power supplies. Thes are some really nice ones probably capable of handling a couple of Kwatts. Im not ready to experiment with them yet. Although this is learning by destuction it's cautious destruction. I will probably take a trip down to the local computer place this weekend and do a little dumpster diving or make a run on the goodwill store and see what I can get for $10. IF you havent figured it out by now I love building things from others discards. When I was in high schooI I built a killer stereo, I thought at the time, from old stuff I found in the dump that was the envy of most of my friends. Ive enjoyed doing it ever since.

Cobbling stuff together is lots of fun. From Pressman's book you can figure out the inductor value.

I'm guessing a powdered iron toroid from the output of a PC power supply would work. Probably need quite a few turns of moderate size ~22AWG magnet wire. Maybe 300 turns... ugh. Makes my hands hurt just thinking about it. I guess a bobbin wound inductor would be better. Gapped ferrite isn't bad!

Check this site http://schmidt-walter.eit.h-da.de/smps_e/smps_e.html

I try to stay away from dumpsters but if I see anything electrical or electronic in one it's neigh impossible.

```

hi everyone:

i designed a new type of regen-reflex radio called the Hellenedyne. it uses a single triode in cathode follower mode at RF and in grounded grid mode at AF. the tube i selected needs only 18 volts of plate. it can be used with low-impedance earbuds for good sound. output is high compared to an Armstrong regenerator. if you love single tube designs you must try this one! explaination and circuit are available at my website:

http://home.comcast.net/~phils_radio_designs/index.htm

regards,
phil :)

PS if you wish to contact me feel free to send an e-mail

From what I gather fro mthe website there is little danger in making L
to large within reason so I can expect my bits and pieces removed from
old power supplies to work. If they dont its probably because its too
small.

Jimmie

The computer aided design was a big help. I figured 16mH. I think I
have something about that size. I have a 20mH choke at one amp that
may work.
What you think Grumpy.

Jimmie

Hello,
I'm looking for some expertise on how to convert the receiver I have, without tuning wheel, in a receiver with tuning wheel. I tryed to install a suitable shaft encoder but it seems to me it need different fw version. Any help?

Claudio

This is just way to cool. I took a 500watt Lambmda 15 volt switcher I
had used to power a solidstate amp and wound another secondary on the
transformer. I lost count of the numer of turns, maybe 100, but
after filtering and rectifying im getting about 450 volts and it has
been running since about 9:30 AM 3hrs putting out 150mA.

These transformers look a little wierd They seem to be two sepated
coils fastened together on a frame. It looks like you could take the

secondary coil off and replace it if you wanted to.
Grumpy , are you familar with this.

Jimmie

That's great news! You could easily buck regulate the +15 down for a filament supply as well.

I've seen transformers with seperate primary and secondary windings. If a company is building s standard product line with various outputs they'll sometimes do that. Although it usually increases the leakage inductance so that's the down side. Sometimes the output inductor and transformer can be combined.

I hope this goes though. I keep getting error 441 so I sent you an email regarding your last post.

Hey Dr. Phil

That's interesting, you state somewhere in that linked article that over 70vdc is dangerous. I use throw away 35mm camera photo flash units that run off of a AA cell and drop the voltage down to 75vdc. I like to use the really old 1 and 3 volt directly heated cathode tubes, like the 3v4 and 1u4 or the 1u5 has a diode in it.

My supply only requires 1 battery.

Thanks for the great article. And the great old technology.

I use wireless headphones when working CW as I find the corded headphones very confining. Also I can hit the sandbox or icebox while the other guy is transmitting.

Wired headphones are (almost) obsolete...

Bob <biascomms@invalid.inv> wrote:

>CW /certainly/ isn't obsolete!

CW is quite obsolete in the commercial radio world. However I agree CW still can be fun to use in the ham radio hobby.

>I can make QSOs with just a few Watts...

I would agree that CW works better than most other modes under adverse conditions. That's one of the reasons I've been using it for so many years. My HOA required stealth antenna is a very poor radiator, and even though I'm running 50 watts, my ERP is probably just a couple of watts...

Perhaps it is your hope that Amateur Radio not be represented or supported?
Perhaps only by the FCC?

I support ARRL because without them we would have been squeezed off the air
a long time ago. The ARRL is full of imperfect people though, and we need
to help out rather than throw monkey wrenches. I don't base my support on
freebies. Germany went fascist for the perks and went to hell over it.

I have remote speakers throughout the house. I have a long mic cord that goes anywhere but the kitchen. It occurs to me that a keyed 1kc tone might be the quick answer though. Software can be brought up in a couple of places to control the radio. Wireless mic and key are the next project.

Actually,  a lot of third world countries still use CW for distress calls,
but who wants to get pulled off course to rescue a bunch of boat people?

I'm sure there are plenty of organizations besides ham radio that would be
happy to step into the power vacuum.  Look at Iraq.  I'm sure ARRL is not
nearly as bad as Sadaam to warrant a scorched earth solution.

Some people in this country actually buy what these people produce.

And some people in this country put jewelry in their noses, lips, ears and other odd places.

Others go out and buy cell phone/TVs and pay $200+ a month for their communications.

Some people build model airplanes from WW2 or do needlepoint or collect antiques as a hobby.

We could write a book full of this stuff.

Try this company.
I have purchased some Cinch/Jones items from them in the past.

> Simply put, there is no reason for a code test in the modern world.

Yes, there is. In ham radio, anyway.

The reason is this:

A license test for an amateur radio operator license should test
things hams actually do on the air.
Hams use Morse Code on the air in 2008.

> If
> someone wants to use CW he simply learns it or fires up his computer.

That same logic can be applied to anything in the written test too, so why have a written test?

> There once were valid reasons to learn the code, but they haven't
> existed for decades.

Some reasons have gone away. Not all. And it hasn't been "decades", either.

> That the code test survived so long was simply ham politics.

Not really. The treaty wasn't written by hams.

> >By testing, we make people prove they actually learned a few things...
>
> When an 8 year old child can pass the Extra exam, I think you can
> safely say that it can be passed without *knowing* the electronics
> theory that it pretends to test for.

How do you know for sure that the 8-year-old didn't know the material on the test?

Bit of history:

Way back in 1948, the old Class B exam was passed on the first try by Jane Bieberman, W3OVV (sk), at the Philadelphia FCC office. She was 9 years old at the time.

In those days, the Class B exams were:

13 wpm Morse Code receiving, minimum 1 minute solid legible copy out of 5 minutes
13 wpm Morse Code sending with a straight key
50 question written exam that included:
- essay questions
- draw-a-diagram (schematic and block) questions
- show-your-work calculation questions
- multiple-choice questions

No published question-and-answer pools. No partial credit. No CSCEs. No Bash books.

Now maybe W3OVV didn't understand every subtlety of every question, but she did well enough to satisfy the FCC examiner.

> >But having observed what happens when people
> >are trusted to learn on their own, (cb as one example),
>
> Darn, if only they had started out with a CB code test
> =A0all would be well now...

Yes, it probably would be.

Do you think amateur radio should be more like CB? One license class, no tests, everybody the same, people trusted to learn what they are interested in and not have to learn stuff...

Yeah, that's been shown to work really well in radio.

I don't think so. Without ARRL there'd soon be no amateur radio. Not as we know it, anyway.

What would happen is that there would be a little change here and a little change there until there was essentially nothing left.

The code test didn't keep the whackos out of the hobby. If that were
true there would be no code-tested offenders on *any* mode.

>maybe W3OVV [9 years old] didn't understand every subtlety
>of every question, but she did well enough to satisfy the FCC examiner.

You could pass the exam without knowing the material even back then.
The current Bash like study materials make it lots easier now though.

>Without ARRL there'd soon be no amateur radio.

Lots of other countries still have amateur radio. No ARRL there...

>Not as we know it, anyway.

That might be a good thing.

Perhaps that includes the USA?  There is a robust draft-horse farming
movement here in Minnesota.

Michael

Why haven't they already stepped and displaced the ARRL then. They should
already be working to take their place so that more people will boycott the
ARRL.

Perhaps because they simply can't handle more than a single issue at a time
(NCI comes to mind).

I think I get it. Would this explain why in a push-pull topology after the transistors have been replaced a couple of times the power supply just keeps failing for no apparent reason?

Are you saying that in other topologies it doesnt saturate or that it doesnt matter if it does?

Ordered Abe's book.

Jimmie

Well I remember repairing Sony TV push pull SMPS I made a living from replacing many a blown PP pair. Sony then went to PP pair in a single package. That reduced the business for me but I had much experience repairing them already. Trick with the Sony push pull was 2% timing components. The PP had to be within 2% of 50% duty cycle. They used a self starting multi vibrator design. After replacing the blown parts I'd power the input up at 20vac and use a 12vdc supply for the start up circuit, Then check the waveform on a scope to make sure it was with 2% fo 50% duty cycle. There was no dead time in the Sony's. They just varied the frequency to regulate the voltage.

I don't know of any ham organization that wants kill the ARRL. My
supposition is that if there had been no ARRL, another group or groups
would have been lobbying in it's place.

>They should already be working to take their place so that
> more people will boycott the ARRL.

Let me try one more time (3rd try). My boycott is purely a *personal*
one to make *me* feel better. I really am not trying to get converts.

I used to make a living selling Cinch connectors.
That part number is for a 10 pin female so any
Cinch number that begins with S-310 can be used
the suffix letters indicate the mount or shell style.
The numbers I remember off the top of my head:

S-310-AB
S-310-SB
S-310-CCE

The SB and AB are chassis mount the rivets can
be taken out and then the socket can be used in
a CCT or CCE style.

the S-310-CCT-K is a locking shell style. With
little clips on the sides to lock the socket in
place to it won't come out.

I used to make a living selling P.R. Mallory
the 3 digit code is the manufacturer, 274
is/was RCA.  And 235 is/was Mallory.
Ole P.R Mallory used to snap up companies
like RMC and Duracell. When he retired they
started selling off all those companies.

I am looking for schematic/ manual for a Lambda LYS-P-15 power
suppply. I bought a couple of these at a hamfest a few years ago and
as I remember they worked before they got put away in storage but dont
now.
Any help would be greatly appreciated.

Jimmie

   Now, Mallory (Capacitors) is owned by Cornell Dubiler.

There were a few other BD tubes as well.
The 6AR8 and 6ME8 are also listed in the RCA receiving tube
manuals along with the 6JH8.  I don't know about current price
and supply on those.

Also check out this link, good info on the 7360 as a mixer.

http://www.mail-archive.com/amradio@mailman.qth.net/msg03105.html
Seems the 7360 performance is poor with IF's above 1mhz.

That poster also claims there is no rejection of either input signal
(grid or deflection plates) offered by the 7360.
Being a balanced modulator, the grid
signal can be cancelled by balancing the plate circuit.
It is used for DSB generation in SSB rigs!

Pete

The writer's an idiot. The 7360 is good to over 50 MHz IF!

What he claimed was that the conversion gain dropped to unity above
that frequency.  That doesn't mean it isn't a good mixer at 50mhz.
Diode ring mixers have a unity (or LESS!) conversion gain, yet they
are very good mixers.

I have to wonder if the guy took a broadband, untuned
PD circuit and tried to use it as a broadband mixer?

If that's the case, then the interelectrode c
apacities would definitely limit BW in a high
impedance circuit, unless they were
"tuned" out using a LC resonant circuit.  I ran into that
headscratcher trying to figure out how to drive the
deflectors using a broadband balun type arrangement;
like was done in the Squires RX.

I get useful conversion gain at higher frequencies (though it's reduced) and it's easily compensated for by the AGC. I found that I needed fairly consistent IF signal levels for best performance of my crystal filters.

I appreciate the conversion /loss/ of diode ring mixers, but I find that amplifying, then attenuating, then amplifying again tends to introduce additional unwanted noise that can be avoided by use of a sensible gain distribution. Diode mixers also don't handle very large signal levels very well, and can produce some very strange results when over driven! I can't really understand the love that some designers have for them.

My newer design approach is to use a switching ring of FETs, but the results still can't match up to the 7360.

Bob

Almost certainly. He was therefore destined to fail completely!

> If that's the case, then the interelectrode
> capacities would definitely limit BW in a high

> "tuned" out using a LC resonant circuit.

Exactly. "Tuning them out" would make the mixer somewhat less "broadband"!

> I ran into that

> like was done in the Squires RX.

I looked at the Squires design, and it was very clever, but seemed to
require some obscure components that were unobtainable.

Topologies like push-pull, half-bridge and full bridge don't require dead time to reset the transformer core. Though that doesn't mean the switch's conduction times can overlap which causes shoot-though current.

I think what kills the push-pull in this case is overlapping conduction times not core saturation.

For amplifier power supplies it would simplify things to do the regulation at a lower voltage and keep the HV parts at a minimum. Phase controlled 60Hz switching is ok but this might be a better way.

There's a use for push-pull or half-bridge or full-bridge where the switches duty cycles are not modulated and the frequency is fixed. The switches run as close to 50% duty cycle as possible without overlap. It's called a "DC Transformer." It's one of the building blocks of compound converter topologies. Handy because it offers isolation and a fixed ratio of step-up or step-down with a DC input and output.

Since there's minimal dead-time and no output inductor is
required. The efficiency can be very high. The control
circuit is an oscillator running at 2F (Like a 555,) followed
by a flip-flop and a couple of gates to insure there is never
overlap. When using MOSFETs an RCD network on their gates
will work, though I favor using logic gates.

So if you built one of these with a 10:1 ratio you could
put 200VDC in and get 2000VDC out. Any regulation or
protection would be done to the 200VDC input. This might
not be a bad idea... your 2KV output stage now consists
of only rectifiers and a capacitor.

Doesn't have to be 200V, pick the voltage that makes it easy.

Just a thought.

Do you use the fets as passive switches, or do you apply power between the source/drain? What kind of fets (IE: depletion mode jfets or enhancement mode mosfets)?

Can you post the 7360 mixer circuit you use somewhere?

BTW these tubes (7360, 6AR8, 6JH8, 6ME8) are sensitive to magnetic fields and need to be shielded for best results. James Millen used to make a mu-metal shield that would fit over tubes this size. I would suspect unshielded tubes could be the reason for the poor results obtained with some of the color tv versions of these tubes.

Also the 7360 is shown as a tetrode, while the color tv tubes are pentodes (ie: they have three grids), but grid #2 is grounded and grid #3 has normal 'screen' voltage applied. Grid #2 is internally connected to the heater or cathode for these tubes.

The conversion gain should be much greater than unity
for any of those balanced mixers. He was doing
something wrong to write statements like those.

Regarding the DBMs, sure they have some loss,
but the losses basically sets the mixer noise figure.
Add a few dB loss for the the front-end preselector
filtering, and may 8 dB loss for the mixer, followed
by a strong, low noise IF amplifier, and your pretty
much good to go, on the HF bands anyway..

DBMs like to be driven by symmetrical
LO waveforms (square wave is great) and the port
terminations are critical as well. My own experience
with them is that the supporting stages also need good

shielding, filtering and bypassing, they are great
harmonic mixers from DC to light!

I'm sure Bob's H-Ring designs are suberb; I've
pretty stopped playing with mixer circuits after the
DBMs became available well over 20 years ago!

Pete

Well if you has the shell,  any S-310 will work. It's all the same
just
the shell or the mounting is different

I'd go wit the S-310-CCT

I was looking at some old UPSs without the big iron transformer and
was trying to figure how they get 60Hz 1KW out of that little
transformer.
The best I an figure is that it works somewhat like a class G
amplifier. In this case the pulse width of the 20Khz or so signal is
being PW
modulated so when the output is intergrated you get 60Hz. If this is
the case I am thinking that UPSs may be hacked into HV power supplies
a lot easier,
safer and better than microwave oven power supplies.

Jimmie

I'm thinking it'd be a rather poor idea to make a reference oscillator for a DDS (or PLL) equal in frequency to an IF somewhere in your radio... right? Since you're just asking for it to get into the IF itself?

In the ideal world, would one choose reference oscillator frequencies that weren't harmonically related to IFs? I've seen those "IF planning" spreadsheets (that calculator where mixer spurs are going to fall), and such a choice seems like a good start.

Thanks,
---Joel Koltner

I would certainly avoid it. With thorough enough shielding you can keep
just about any signal out of any circuit, but there's no need to tempt fate.

If you have a decent receiver, you would need over 100db of isolation.

That is very hard to get in a small space. One of the arts of receiver
design is taking care that all of the frequencies and mixing products
don't show up in the passband.

rec.radio.amateur.policy has become unusable for any type of discussion due to the single handed take over by one individual. He has so many user names that blocking him becomes a chore in itself. The hundreds of posts that he makes in a day on every thing else that is posted was the reason that rec.radio.amateur.moderated was formed.

The original no code Tech had no HF privileges since international treaties
required code for frequencies below 30 MHz.

Today's Technician now has all the HF privileges of the Novice class. Those
privileges have now been expanded also. On 40m, 15m, and 10m, their CW
privileges now cover the same spectrum as the General class license.

This is an old argument. It is the 'weeder' argument. A code test will weed out all the bad apples. It hasn't worked in the 50+ years I've been a ham. There have always been ham whackos.

In the 60's I listened to a daily net called WCARS (West Coast Amateur Radio Service- called Westcars) on 40M SSB in CA. They suffered daily harassment, carriers, unidentified obscenities ect. 75 meters SSB was bad then also. The IDed offenders were all code tested hams, likely the unidentified nuts also.

> A VE team around here got busted selling licenses.

There has always been some cheating on tests.

In the 50's you could get a Tech license by mail. Your buddy ham could give you the code test and any adult could proctor your exam. I don't have to tell you there were some no-code open-book Techs licensed.

And I think Bash came out in the 70's. That's where they were stealing the FCC exam questions and answers and publishing them in a book. (Questions-answers are SOP now but not then.

>Maybe you can think of some test or hoop besides CW to discourage the people
>that act out like morons because they lack self-control.

Sure. A psychology test...

Except the Russians. They were still using tube gear in their military back in the mid 80s. Not susecptible to EMP (electromagnetic pulse) from a nuke going off. They may STILL be using tubes...I'm out of the loop since leaving the military in the late 80s...

Probably one reason there aren't more tube projects in QST, etc. is that nobody is left who wants to learn an "obsolete" technology and the old timers aren't going to bother writing about them because all they would hear is bitching about how someone wrote an article on old technology and wasted the pages in QST, etc. Just a guess.

I did, and it didn't "cost a fortune". I got the crystal filters at a Rally, I had many of the other components in the junk boxes, and I just had to buy a few valves and some coil formers. I built the cases myself, and the internal module boxes are just soldered up PCB material. I found the reduction drive in a junked HRO, and bought the tuning capacitors very cheaply. Frequency indication and relative signal strength are shown on an LCD display.

They still do, in /professional/ receivers, though it's becoming rare due to the component cost. I also find that it's much easier and cheaper to go QRO with valves than it is with semiconductors. TV sweep tubes powered many of my HF amplifiers over the years!

> Even ham magazines print mostly solid state articles using modern

Most of them are scared that they'll get sued when some know-nothing-numpty gets bitten by the HT! I use semiconductors where they're appropriate and use valves when they are the best way to get the results I want. I really don't care about your perception of nostalgic engineering - I get better results with my hybrids than are /possible/ with semiconductors alone.

Believe me, I've tried most of them, and some are actually quite good. However, they simply don't match up to the performance of the receivers I have here - I've got my own hybrids, a Plessey PR 155 (probably the best of its genre), a couple of Eddystone boxes and a couple of "Sailor" marine rigs. There's /nothing/ that's come from Asia that can match /any/ of them!

>>our hobby, and build the gear myself!
>
> Building is but *one* facet of the hobby. Professional engineer hams
> capable of designing and building transceivers are a but very very
> tiny part of the hobby...

Not over here! Many Hams here are disappointed with the high-priced junk that comes from Asia, and find that it's very satisfying to build and operate proper home made gear. We also have a lot of QRP operators (mostly under 1 Watt) that simply won't be heard by those equipped with the Asian black boxes!

>>Not at all - they [Asians] /still/ can't make a good mobile phone! 8-)

> As I said prejudiced...

Oh dear. Perhaps you can't understand what's been said: The Asians are great at making stuff smaller and cheaper (I used to design for Panasonic), but they're *not* innovators, and everything's made _down_ to a price rather than _up_ to a specification. I find that attitude to be frustrating, and many companies I work for have abandoned that paradigm, and want to produce the best equipment, whatever the cost. That's why Nokia and Motorola make the best mobile phones, and Sony had to buy Ericcson in an effort to play catch-up!

There's no actual prejudice involved at all, just a simple statement of facts!

There are several reasons you don't see much manufactured tube gear, such as a "modern" version of the TS-520S.

The first reason is cost. Getting tubes and tube-type parts made in the quantities needed would be more expensive than using solid-state. Manufacturers can't use parts found at hamfests/rallys/on eBay, and gearing up to have stuff made custom is expensive and chancy. The complexity of the rig in ways such as needing both high and low voltage supplies adds to the cost, too.

The second reason is size.

The third and most important reason is that tubes have become electro-politically incorrect. Admitting that an old technology can do something - anything - better than a new one just rubs people the wrong way. Putting a 7360 in the front end of a "modern" transceiver would be an admission that there has been a better solution around for decades, and a lot of folks don't want to admit that.

As a case in point, look at the Elecraft K2. When it was introduced back in 1999, it blew away much more expensive rigs in many performance criteria. Yet its hardware design is much simpler than almost anything else on the market that comes close to its performance. Worse, it turns the usual marketing ideas upside down in that the basic rig is QRP and CW only *kit*, with 100W, SSB and many other features as add-on options.

The conventional wisdom of 1999 said there was no market for such a rig. But with almost no advertising over 6000 have been sold. And the product line has grown in several directions since 1999, including the K3, which has sold over 1500 units.

> > Even ham magazines print mostly solid state articles
> > using modern solid state parts,

How many complete multiband multimode transceiver projects have you seen in US ham magazines in the past 10 or 20 years?

> > which is right since hams should learn to use
> > modern technology.

But who decides what is "modern"?

Is SSB "modern"? It was first used on the air in the 1920s, first used by hams in the early 1930s, and has been commonly used by hams for 60-odd years. Almost no other service uses SSB anymore.

Is AM "modern"? It was first used on the air in 1900, and by 1906 was being heard across the Atlantic. It was common by the 1920s.

How about FM? It's only a couple decades newer than AM. Repeaters were in common use in the land mobile services in the 1950s.

RTTY dates back to WW2, and although the mechanical teleprinters have been replaced by computers the coding and FSK methods used are basically unchanged for half a century plus.

Most of the technologies we hams use have long been abandoned by other services, or are simply kept alive because of the large installed base of users - which is slowly dwindling.

 of the loop since leaving the military in the late 80s...

EMP was one reason, but there were others. A big one was that they had the industrial capacity to make high quality tubes in huge numbers, but not semiconductors, so the solid-state was reserved for where nothing else would work.

Not exactly.

QST is a general-purpose magazine; the technical stuff largely goes to

QEX., which was created just for that purpose because the QST staff got and keeps getting complaints that QST is "too technical" (!).

Way back in 1989 a magazine called "Electric Radio" appeared, and is still going strong. It's a small mag that specializes in hollow-state gear, but there's plenty of interest and homebrewing going on.

Most of all, the internet has made it possible to put far more info out there than could fit in a magazine, without the cost and bother of printing and postage. Even I have a webpage (google my call) with a picture and description of my shack and rig. The resources out there are incredible; the main problem is getting through it all!

If I'd have to guess, Hank, I would say that cap was made in the 12th week of 1981. That's according to the last 4 digits.

James

And it has some validity.

> A code test will weed out all the bad apples.

No test will weed out all the bad apples. Particularly not a test that
is given one time only and then is good for life.

Consider all the testing that doctors and lawyers go through to get
their licenses. Yet there are still some doctors and lawyers who are
"bad apples". That doesn't mean the testing should be eliminated since
it doesn't do a perfect job!

> It hasn't worked in the 50+ years I've
> been a ham. There have always been ham whackos.

Of course. No test or screening method is perfect.

But it is human nature that people will value something more if they
have a personal investment in it.

But was it as bad as in, say, the 1990s? As bad as the W6NUT repeater,
say?

> The IDed offenders were all code tested hams, likely
> the unidentified nuts also.

But you don't know for sure about the unidentified ones. Plus in those
days all US hams were allegedly code tested.

Most of all, note that the bad behavior you cite was all on voice, not
CW/Morse Code. The bad apples may have passed a code test at one time
or another, but they weren't *using* the mode!

> > A VE team around here got busted selling licenses.

> There has always been some cheating on tests.
>
> In the 50's you could get a Tech license by mail. Your buddy ham > could =
give you the code test and any adult could proctor your
> exam.

The exam procedure varied over time, and by the mid-1950s the person giving both code and written tests had to be an FCC licensed amateur or commercial operator. But it was all on the honor system.

> I don't
> have to tell you there were some no-code open-book Techs
> licensed.

More importantly, there was the Conditional license until the mid-1970s. The Conditional was a by-mail version of the General, if you lived far enough away from an FCC exam point. From ~1954 to ~1964 the distance was only 75 miles, and there were a *lot* of Conditionals licensed.

One "trick" I heard of, but was never able to verify, was that a would-be ham would give the address of a vacation home, friend or relative in the "Conditional zone" in order to get a Conditional license. Then, after some time passed, the ham would "move" to his/her actual address.

One of the big reasons for all the screaming about "incentive licensing" was that in order to upgrade, Conditionals would have to take tests at FCC offices in front of FCC examiners.
>
> And I think Bash came out in the 70's. That's where they were
> stealing
> the FCC exam questions and answers and publishing them in a
> book.
> (Questions-answers are SOP now but not then.

Yes, the infamous Bash books appeared in the 1970s.

What Bash did was to ask people leaving the exam sessions to recall whatever they could about the questions. He may have even sent folks to exam sessions simply to memorize what they could of the exams. He allegedly paid $1 per question reported. Over time he collected enough bits and pieces to reconstruct the entire exam set.

In doing so, Bash revealed the big secret of the FCC exams: There were only a few different versions of the various tests! That was why there was a 30-day wait to retest.

Some in the FCC wanted to prosecute Bash, but the FCC leadership overruled them. Then budget cuts in the early 1980s forced FCC to create the VE system, and the Q&A became public. Which put Bash out of business.

> >Maybe you can think of some test or hoop besides
> >CW to discourage the people
> >that act out like morons because they lack self-control.
>
> Sure. A psychology test...

It should be remembered that one of the factors which drove "incentive licensing" and other testing initiatives was the cb experience. FCC never imagined that huge numbers of people would simply ignore the rules, but within a few years of its creation, 11 meter CB was simply out of FCC's control. Breaking the rules became much more common than keeping them, and to this day FCC has not gotten the upper hand.

Now, why were hams so well-behaved compared to cbers, even when FCC spent far less resources to enforce the rules on the ham bands?

> There has always been some cheating on tests.
>

Maybe you hung out with a different crowd than I did. All my study was out of Engineering classes and ARRL Handbook and License manual for the regs. I was taught the code from a CW op who officiated my Novice exam. We didn't proceed until I could do on the air QSOs in front of him on the club station. And by the way, everyone that I studied and did code practice with, got ham tickets. Even a Mexican kid who barely spoke English. Those that bitched and moaned and threw tantrums over it, didn't want to after all. Glad not to have them.

You are correct that "weeder" tests can't be 100% effective. But if you think that they don't have an impact, then why test at all? If nothing is 100% effective then game is up? No more testing then? They went that route with CB and they couldn't even give people a litteracy test. I.E. getting them to sign a paper stating they would abide by the rules. FCC gave up on it and let it go fallow. The result was dealing dope and scoring hookers in between hetrodynes, pornographic tirades and general orgies of funny noises, wailing and knashing of teeth of the damned. The rest were chased from the band.
>
> >Maybe you can think of some test or hoop besides CW to discourage the people
> >that act out like morons because they lack self-control.
>
> Sure. A psychology test...

So, essentially a pseudoscientific approach? Ridiculous. Lets keep it all above board. Although Psychology is a fascinating study, there are aspects that can lead one astray. If my previous post was a psychology test, I might have failed you.

The whole Psychology idea reminds me of the Russian fake spyware scanner that pops up and tells you that you're infected and you will have to send $50 and download the cleaner to fix you up. You the pay the money, install the program and you're hooked up with endless spyware and adware until you can't boot up anymore and wipe your hard drive and reinstall Windows. No Thanks. You should know that answer cuts both ways senior. Even if you're buying the Psych.

All you have to do is make it difficult for those with short attention spans and little patience. Then follow up with peer pressure. But you have to ignore the tantrums and crying jags and reinforce good behavior. Until parents and governments realize that fact, society will continue to go fallow. Peer pressure is what happens when people begin imitating one another. That is how whole groups go nuts. It is how great teams succeed. It doesn't happen overnight. It is the result of people pushing the envelope and others tolerating or encouraging it to the point where the behavior becomes commonplace and acceptable and encouraged. I never spent any time on Westcars. Glad I never spent time in Nazi Germany either.

We don't have a code test anymore so it is a moot point. It is left to peer pressure and the skills tests. I will still use Morse Code because it is useful. It won't be useful if no one knows how to do it. It is even more useful because other people who use it aren't anything like your 75m phone Westcars people. This is all the proof I need that it works. But I guess you don't have that proof, do you?

Agreed. Tranceivers of today are generally much less costly (and have many more features) than the tube gear of the past. Progress is good.

>The second reason is size.

Agreed. My 100W mobile rig sits on my dashboard. Try that with the
tube gear of the past. Progress is good.

>The third and most important reason is that tubes have
>become electro-politically incorrect.

Tubes are electro-politically incorrect?? Now that is funny. The
conspiracy theory? Black helicopters.... 8-O

>As a case in point, look at the Elecraft K2...
>it blew away much more expensive rigs in many performance criteria.

How many tubes do they use to get this performance?

>But with almost no advertising over 6000 have been sold.

Have you contacted them and suggested your 7360 tube front end idea
for use in the next model of the K2? How long do you think it would
take for them to stop laughing...

Yes tubes are still quite valid in ham amps.

>TV sweep tubes powered many of my HF amplifiers over the years!

Remember those sweep tube KW amps? What was it, 6 tubes in parallel?

I think my old Swan 350 (nicknamed Swan 3-drifty for good reason) used
sweep tubes. Kept within specs they lasted a long time but they didn't
seem to take much out of resonance abuse.

And my Heath mono-banders, wasn't that a sweep compactron?

Yes I was a sweep tube fan also...

>Believe me, I've tried most of them, [Rice Boxes]

You've tried *most* of hundreds of models and brands? That seems to be
another unsupportable exaggeration.

I forgot about EMP. And I guess that is a quite valid reason for using
tubes in emergency gear. I do remember that EMP was one of the things
discussed for ham emergency gear.

I'm sure that our (US) military protects for EMP, but I doubt it is by
using tube equipment. Likely something more modern. Fancy Shielding?
Perhaps you know the technology currently used?

In Desert Storm they were breaking out KWM-2a to replace radios that were
getting nailed from static in the blowing sand.

Yup

At one point, sweep tubes were available cheaply at TV shops so the designs were at the edge of meltdown. It was neat to have a 350w pep radio, but that was asking way too much. I saw a lot of Swans and others that would break into oscillation with the least provocation. I knew one guy who was a regular customer of the Radio Shack Lifetime tubes. Give me a set of 6146s any day. Conservative designs yet economical. I can always follow up with 811s for more power. Those guys are still cheap and seem to last forever. If you have to plug it in the wall anyway, might just as well be tubes.

Exactly. Passing a license test does not prevent bad behavior.

>Most of all, note that the bad behavior you cite was all on voice, not
>CW/Morse Code. The bad apples may have passed a code test at one time
>or another, but they weren't *using* the mode!

Exactly. Passing a code test does not prevent bad behavior.

>The exam procedure varied over time, and by the mid-1950s the person
>giving both code and written tests had to be an FCC licensed amateur
>or commercial operator. But it was all on the honor system.

Not quite correct. I suppose even historians get it wrong sometimes.
Course I knew the mail order license procedure pretty well since I did
it twice, once for Novice and again for Tech.

The following could give the mail order code test:
An Extra, Advanced, or General Class licensee, or
a Commercial Radiotelegraph Operators licensee, or
a Government employee of a manually operated radio telegraph station.

And as I said before *any* adult (at least 21 then) licensed or not
could give the written exam.

>What Bash did was to ask people leaving the exam sessions to recall
>whatever they could about the questions.

Another piece of history I lived. I used Bash for my Advanced.

>Then budget cuts in the early 1980s forced FCC to
>create the VE system, and the Q&A became public.
>Which put Bash out of business.

Interesting how what was called cheating then is now a legit exam...

>Now, why were hams so well-behaved compared to cbers,

Because the hams had to ID? If people know who you are many act
better. And if they didn't ID no one would talk to them. Some did
bootleg though with false calls. I'll admit to bootlegging on CW
before my Novice ticket came. My buddies name was Kent, so I used
K7ENT. It wasn't issued yet so no harm no foul...

"JB" <nospam@goofball.net> wrote:

>At one point, sweep tubes were available cheaply at TV shops so the designs
>were at the edge of meltdown.

I worked in a TV shop after high school for gas money. Sweep tubes were very expensive as tubes went in those days. But I got mine and most of the rest of my ham parts from old discarded TV sets.

>Swans and others that would >break into oscillation

My Swan was drifty as I said. It was a heat problem with the VFO coil compartment. The osc was solid state, the only transistor in the whole rig. I solved it by building an external VFO.

>I knew one guy who was a
>regular customer of the Radio Shack Lifetime tubes.

In the 50s there was a tube company called Major Brand Tubes. They were mail order and had a lifetime tube guarantee. Their tubes seldom lasted more than a month in a TV, and they were good to their word. Send them the old tube and they sent you a new one free, you paid postage of course. Well after 5 or so replacements most people finally gave up. A real racket.

>Give me a set of 6146s any day.

I built a single tube 6146 transmitter. I used a voltage quadrupler direct from the 110V for the high voltage (no HV transformer needed). It was a simple high powered xtal controlled oscillator. I used it as a Novice. I don't remember the exact power input now, but it was probably around 50 watts. I just had to be careful which way I plugged it in the wall socket. Wrong way and fireworks...

>CGS192T450X5L3PH
>235-8112K
>Thanks

I have three screw terminal Mallory caps with the following markings:

MALLORY
MADE IN U.S.A
TYPE CGS
30000MFD 15VDC
POS + 85C
MAX SURGE 20VDC
95661319
235-8102K

MALLORY
MADE IN U.S.A
TYPE CGS
29000MFD 15VDC
POS + 85C
MAX SURGE 30VDC
CGS293U025R4C3PH
235-8532K

MALLORY
MADE IN U.S.A
TYPE CGS
21000MFD 16 VDC
POS + 85C
MAX SURGE 20 VDC
CGS213U016R3L
362 8906 56699

They all date from around the early 80s.

Here they are pictured among Sprague caps of the same vintage:
http://www.users.on.net/~fzabkar/screwcaps70.jpg

I'd say that 8112 is a YYWW date code.

AJ Lake wrote:

> I'm sure that our (US) military protects for EMP

No it doesn't and never has. The Russian plans for preemptive strikes included high air bursts over major centres of population to cripple communications. The Soviets /knew/ that the USA was entirely vulnerable to EMP, and still is.

> Perhaps you know the technology currently used?

Yes. We Brits have military communications equipment to deal with EMP - it's /all/ valve based. Trying to protect semiconductor gear against EMP is like trying to protect telephone equipment against lightning - entirely futile!

Not at all - I used to examine equipment for a well-respected ham magazine.
Most of the Asian gear is junk.

>> We also have a lot of QRP operators (mostly
>>under 1 Watt) that simply won't be heard by those equipped with the Asian
>>black boxes!
>
> Now you're being funny. Cause you can't be serious, can you...

Funnily enough, I worked a Canadian last night on 14 MHz, with each of us using less than 5 Watts. His signal was entirely inaudible on the extremely expensive Rice Box I've just repaired for a friend, but was clearly audible despite fierce adjacent Italian QRM on my hybrid RX (and on the Plessey).

Not exactly. Passing a license test does not prevent *ALL* bad behavior. Just because a test isn't perfect doesn't mean it has no effect.

> >Most of all, note that the bad behavior you cite was all on voice, not

Not exactly. Passing a code test does not prevent *ALL* bad behavior.
Just because a test isn't perfect doesn't mean it has no effect.

> >The exam procedure varied over time, and by the mid-1950s the person

> An Extra, Advanced, or General Class licensee, or
> a Commercial Radiotelegraph Operators licensee, or
> a Government employee of a manually operated radio telegraph station.

Yep.

> And as I said before *any* adult (at least 21 then) licensed or not

Been that way for more than 25 years. Complain to FCC; *they* changed
it.
>
> >Now, why were hams so well-behaved compared to cbers,
>
> Because the hams had to ID?

CBers had to ID too. They had licenses, callsigns and everything.
Didn't stop them from misbehaving. Shall we eliminate callsigns and
licenses because they don't prevent all bad behavior?

> If people know who you are many act
> better. And if they didn't ID no one would talk to them.

Why didn't cbers do the same thing?

>=EF=BF=BDSome did
> bootleg though with false calls. I'll admit to bootlegging on CW
> before my Novice ticket came.

Why? Couldn't you wait?

> My buddies name was Kent, so I used
> K7ENT. It wasn't issued yet so no harm no foul...

It was wrong nonetheless.

The way something goes bad is often not by massive changes but a
little here and a little there. That's how cb went downhill - a little
extra power here, a non-ID there, a cussword here, a skip contact
there, and pretty soon playing by the rules was extinct.

Nope, no idea. When I was in the Air Force working on aircraft comm radio equipment, "they" told us if a nuke went off, our radios would most likely not work. I don't think fancy shielding would work since all radios I know of have a hole in the shield where RF and EMP can enter. It used to be called the antenna port. Not sure what they call it in "modern" equipment...

When I was still in the USAF, we had our EC-135 and RC-135 aircraft that still had some tube type radios on at least HF and UHF bands, ie 618-T and ARC-34...but...they also had modern radios such as the ARC-190 HF set. I loved the ARC-190 (Collins). It was a nice radio to use and work on. Still see them installed on at least National Guard KC-135s when I get aboard at airshows.

I did some work on simulated EMP back in the 80's (when I was wearing a different engineering hat), and we found that there's /nothing/ that will protect semiconductor equipment against it.

We used very high voltage discharges (at the City University High Voltage Lab in London), and we destroyed all sorts of gear! The original plan was to examine resilience against lightning discharges, but later on the experiments were expanded to cover EMP. We found that "hollow-state" gear could withstand quite a lot of abuse and continue to work, whereas the solid-state equipment would die at the slightest provocation. This had /very/ serious ramifications for the "defence industry".

I've recently found another application that's best serviced with valves ("tubes" - U.S.). A friend of mine is responsible for the maintenance of a number or airport NDB units. The ones they had were solid state, and would quite regularly get fried by static or lightning. Over the last few days we've begun the design of a valve replacement for the "hot" end of these things. It's not difficult to get a few tens of Watts at MF with valves!

Bob

Yes, amateur HF transceivers are generally less expensive to buy new when you adjust for inflation. But at the same time there is far less really-inexpensive new gear, and working on it yourself is much more involved. Plus many "older" SS rigs are difficult to repair because they used custom parts for which the only source is another rig of the same model. A ~50 year old tube rig can be easier to fix up than a ~25 year old SS rig for these reasons.

There is also the fact that in many situations it's better to have good basic performance rather than "features". Many "modern" rigs include lots of "features" because they are easy and inexpensive to include, but lack basic performance that was common 40+ years ago.

So while there is progress in cost and features, it comes at a price in other areas.
>
> >The second reason is size.

But simply making a rig small isn't always progress. For mobile/portable, small is good, but in the ham shack it can be a bother because the displays are hard to read, the controls tiny, and many functions are buried layers-deep in menus.

I'd rather have a rig with a decent front panel than one that fits in a shirt pocket.

No, it's a fact. Your response proves it.

> >As a case in point, look at the Elecraft K2...
> >it blew away much more expensive rigs in many performance criteria.
>
> How many tubes do they use to get this performance?

None - for the reasons listed above.

You ever use one? I have. They're very good.

> >But with almost no advertising over 6000 have been sold.

See? You're saying tubes are electro-politically incorrect.

---

btw, the all-time DX record for a radio built by humans is held by a tube transmitter.

I was working in the manufacturing of new tube type military equipment
(such as the APS 94 side looking radar) into the late 60s. I left the
electronics industry in 68 for an unrelated field and never kept up on
military gear after that.

>I loved the ARC-190 (Collins). It was a nice radio to use and

Collins was always nice gear, either in or out of a military skin.

The only plan I knew of was to keep nukes from going off in the first
place.  I'd guess that since the EC-135s (Airborne Command Post) had
tube radios for at least HF, they would be able to communicate back to
Washington with those...

It is a YYMM date code. I have several pieces of vintage medical electronics equip, and the date codes on the Mallory caps all match closely the date codes on other parts.

Then how do you account for the "32" in "235-8532K"?

Here are two more caps, with date codes of 7945 and 8102:

MALLORY
MADE IN U.S.A
CGS591T200R3C3PL
590MFD 200VDC
POS + 85C
MAX SURGE 250VDC
1014861-00
235-7945K

MALLORY
BIONOL
CAPACITOR
6MFD
660 VAC
60 HZ NO PCBS
95686701
37NB6606
PROTECTED
C 200 AFC
64591 PTD
8102-1

Yes, they do. However it's one thing to know that cheating exists as a general rule, and a very different thing to cite specific instances of cheating. How much actual cheating on the ham license tests went on back in the pre-VE days? How much actually goes on today? I don't think anybody really knows.

I do know this, however:

(in this discussion, the "Conditional distance" is how far from an FCC quarterly exam point you had to live in order to get a license by mail. Distances cited are "air-line" distances, not driving distances)

Before about 1954, the "Conditional distance" was 125 miles, and FCC gave Novice and Tech exams at their offices. Plus if you had a by-mail license and moved to within the "Conditional distance", you had to retest in front of an FCC examiner within 90 days or lose the license.

Then for about ten years the "Conditional distance" was only 75 miles and the retest-if-you-move requirement went away. FCC also made all routine Novice and Tech licenses by-mail, regardless of distance. A considerable amount of CONUS was thus Conditional country.

About 1964 the FCC increased the Conditional distance to 175 miles and increased the number of exam points. Almost none of CONUS was Conditional country after that change.

A weeder test can be relevant. And given the number of amateurs actually using Morse Code on the air, it's a relevant test for an amateur radio license.

> > Although Psychology is a fascinating study, there are aspects...

> I was being funny with the psychology testing thing. I didn't think
> you'd really take me seriously.

In a way, a big part of the testing is psychological. If we could
trust everyone to learn the technology, operating practices, rules and
regs as needed, there'd be no need for a test. By testing, we make
people prove they actually learned a few things, even though the
testing is far from comprehensive and doesn't test if the person
understands the material. But having observed what happens when people
are trusted to learn on their own, (cb as one example), testing seems
to be a good idea.

It IS YYWW (that is year and week)
so....235-8532 means 1985, 32nd week. That is why the K is there...

Syl

I agree that it is YYWW, but I don't understand what you are saying the reason is that the "K" is there? Why is the "K" there?

That's where I figured you were headed with the "K", but typically the YYWW date code, as used on semiconductors for example, is used without a format indicator, in fact IIRC some versions of the YYWW date code scramble the digits in one way or another to obscure their meaning.

I wonder if the "K" might not have another meaning, such as a code to indicate which of several factories the device was produced in? If that is the case, the fact that "K" is the last letter in "week" might just be a coincidence.

> >> There has always been some cheating on tests.
> >Maybe you hung out with a different crowd than I did. �
>
> I hang out in the real world. Some people do cheat.

Yes, they do. However it's one thing to know that cheating exists as a general rule, and a very different thing to cite specific instances of cheating. How much actual cheating on the ham license tests went on back in the pre-VE days? How much actually goes on today? I don't think anybody really knows.

I do know this, however:

(in this discussion, the "Conditional distance" is how far from an FCC quarterly exam point you had to live in order to get a license by mail. Distances cited are "air-line" distances, not driving distances)

Before about 1954, the "Conditional distance" was 125 miles, and FCC gave Novice and Tech exams at their offices. Plus if you had a by-mail license and moved to within the "Conditional distance", you had to retest in front of an FCC examiner within 90 days or lose the license.

Then for about ten years the "Conditional distance" was only 75 miles and the retest-if-you-move requirement went away. FCC also made all routine Novice and Tech licenses by-mail, regardless of distance. A considerable amount of CONUS was thus Conditional country.

About 1964 the FCC increased the Conditional distance to 175 miles and increased the number of exam points. Almost none of CONUS was Conditional country after that change.

you
> >think that they don't have an impact, then why test at all?
>
> Weeder tests keep failures out for *no reason*.
> Relevant tests keep failures out for a *good reason*.

A weeder test can be relevant. And given the number of amateurs actually using Morse Code on the air, it's a relevant test for an amateur radio license.

> > Although Psychology is a fascinating study, there are aspects...

> I was being funny with the psychology testing thing. I didn't think
> you'd really take me seriously.

In a way, a big part of the testing is psychological. If we could trust everyone to learn the technology, operating practices, rules and regs as needed, there'd be no need for a test. By testing, we make people prove they actually learned a few things, even though the testing is far from comprehensive and doesn't test if the person understands the material. But having observed what happens when people are trusted to learn on their own, (cb as one example), testing seems to be a good idea.

73 de Jim, N2EY

Psychology has to do with everything pertaining to human behavior.

Back in my creative writing days, I wrote a research paper on peasant rebellions at the height of the Rodney King beating riots.

In a study of numerous uprisings, rebellions, disturbances and other civil unrest in old times, the conclusion was that the masses indeed require authority and pressure in order to avoid self-destruction. It was found time and again, that these disturbances were most often due to issues of poor morale reinforced within the affected group rather than a righteous rising up against persecution, exploitation or to redress some wrong. Most often the victims were random targets of widespread violent outbursts during these disturbances rather than any defined enemy. Essentially, the Devil has his day. This mentality also carries over to individuals, where perceived pressure or persecution results in school shootings and things like that, where the self-destructive urge is externalized to random targets, or targets of opportunity, rather than a defined enemy. So I suspect this is known to others who can incite such behavior simply by fomenting dissension or planting seeds of discontent, then backing off to watch the outcome in complete safety, thus using crowd and individual Psychology to promote terrorism and destruction as a means to some end.

The whole problem with instituting and maintaining authority though, it how to keep it on the righteous path. In the final analysis, God is the only hope, but only if we spread the word.

I'm pretty sure it is a coincidence. I have only ever seen such indication
on some Philips equipment where the letters KW (kalenderweek,
kalenderwoche) are printed in front of a 3 or 4 digit code. Every single
other piece of equipment I ever saw with such a code only has letters with
another meaning in front of or after the date code.

Could well be but so far only found K and was told so.

I was also told the first 3 digits where the factory ID,
can anyone confirm this?

Q: to OP. What country of origin is the cap from?
Could it be a code for country of origin? Like Canada, US...

Syl

I never saw where the neutral and ground tied together. The closest
thing I could see was on the HV side of the transformer where one side
is tied to ground. This is OK. I did find in another service manual
where it warned about not having the mounting screws to the power
supply fastened tightly while servicing. Thats almost funny. Probably
a good idea to use this on a GFCI circuit.

Anyway I came across some 120/240 to 240/480 volt 2KVA transformers I
had. This got me thinking that it may be at lot of fun building a
switcher when you had 600VDC at a few amps to switch. Coming up with a
transformer may be fun.

Jimmie

N2EY@aol.com wrote:

>A weeder test can be relevant.

The trouble seems to be that we have different ideas of what a "weeder test" means. I could find no specific definition in any reference material, so I'll just no longer use the phrase.

Simply put, there is no reason for a code test in the modern world. If someone wants to use CW he simply learns it or fires up his computer. There once were valid reasons to learn the code, but they haven't existed for decades. That the code test survived so long was simply ham politics.

>By testing, we make people prove they actually learned a few things...

When an 8 year old child can pass the Extra exam, I think you can safely say that it can be passed without *knowing* the electronics theory that it pretends to test for.

>But having observed what happens when people
>are trusted to learn on their own, (cb as one example),

Darn, if only they had started out with a CB code test
all would be well now...

Maybe. Nobody really knows; the treaty in place at the time prevented
it.

> It would have been scary to even express those thoughts aloud
> in those days, considering what you hear now, 50+ years later...

Not at all. As early as 1936, there were ideas put forth for a
nocodetest amateur license in the pages of QST. (The 1936 idea was for
a basic 5 and 2-1/2 meter license that would allow a low-power local
communications without a code test).

But whenever the discussion came up, the overwhelming majority opposed
the idea.

> >> I haven't been an ARRL member since the dark days.
> >When were these "dark days"?
>
> Incentive Licensing. I have always voted with my wallet.

So for something done 40+ years ago, by folks who are mostly now dead, you still hold a grudge against the League. Interesting.

Oddly enough, btw, the League was not the only nor the first to propose a return to a more-progressive license structure in 1963. There were at least ten proposals, some submitted before ARRL's.

Ironically, the original 1963 ARRL proposal simply called for a return to the pre-1953 rules where you needed an Advanced or Extra to use 'phone on most of the HF ham bands.

btw, one of the driving forces behind the changes were letters received by FCC from *nonhams* complaining about the relative techical ignorance of many hams of the day. Those letters essentially said that while it used to be that a ham could be counted on to be reasonably qualified in technical and practical knowledge of radio, the early 1960s version could not. Don't know how true that was but it sure got FCC's attention.
>
> >The license is for operating, not building.
>
> The Technician was meant for those who were more interested in VHF/UHF
> experimentation than HF operating.

But only the kind of experimentation that requires operating. Anybody can build practically anything radio they want in their basement; the license is only needed to put it on the air.

The license is for operating, not building.

IMHO the social-engineering experiment of the Tech license just didn't work. The original Technician (220 and up only) got very few takers until 6 and 2 meters were added. This was due in large part to the fact that, at the time, there was no manufactured ham gear for 220 and up. And througout its history, most Techs have not been experimenters in the way that FCC envisioned.

What's worse is that the Tech license, even before it lost its code test, created a divide in amateur radio between those who had HF and those who didn't.
>
> >The basic argument against the code test comes down to this:
> >Why should anyone have to learn it if they don't intend to use it?
>
> I've heard that argument, but that's not why they quit the code test.

Yes, it is. It's what's behind every argument given to remove it. People who were going to use the mode don't care about a basic test of the mode at all, they just pass it and move on.

> The reasons for a code test that once applied are no longer valid.

Some of the reasons are no longer valid.

> No
> more military CW. No more ship to shore CW. No more WW2 ops needed.

Actually, Morse Code was in regular US military use long after WW2. At least into the late 1960s for the US Navy and into the late 1990s for the US Coast Guard. And there is still some use of Morse Code for maritime use. But very, very little.

More important, those reasons aren't the only ones, nor even the major ones, to have a code test. Even in the old days, most hams would never be military or commercial radio operators, so why require a code test for the few who would be?

The main reason to have a test for something to get a ham radio license is because *hams* do the thing, not because other radio services do the thing, or do not.

> Ect ect ect. CW is now really obsolete for anything but hobby use.

Did you see the article about the ham who was injured while hiking in the Pacific Northwest, and called for help using CW? Just happened a few days ago. Broken leg in a situation like that is a lot more than "nothing but hobby use".

> Making involuntary human modems has little value to the government any
> more.

Being a skilled radio operator isn't being "an involuntary human modem".

What's really changed is that the idea of needing "radio operators" at all. Look at what has happened to commercial licensing, for example.

> >What happens is that the argument, taken to its logical conclusion,
> >says there should be no real test at all.

> The ham test should be about *modern* technology.

Why? With most ham gear today, there is no real need to understand how the rig works in order to use it. Most have no real tune-up adjustments at all.

And who gets to decide what is "modern" anyway? Radio today is mostly VHF/UHF, not HF. It's mostly channelized, too, and highly automated. Most radios today don't even have a tuning knob!

> Testing about past
> obsolete technology and practices such as tubes, mechanical RTTY, and
> code ect just doesn't make sense.

Who decides what is "obsolete"?

Very few hams today use mechanical RTTY machines, so that technology isn't on the test. But the basic technology - FSK 5-level Baudot-coded RTTY - is still in wide use by hams, and is on the test.

Most hams nowadays only use tubes in high power RF amplifiers. A smaller number use tubes for other applications, including entire tube-based stations, but their number is relatively small. So there are only a few tube questions (if any) on the test.

But Morse Code is in wide use by hams on the ham bands. It's not "obsolete" at all. On the HF bands it is second only to SSB voice and is far ahead of many other modes in popularity.

Shouldn't a license to use an amateur station include tests on what amateurs actually do?

What really killed the code test, IMHO, is that a few people complained loud enough and long enough about it. And if you read their complaints, you see that what they're really saying is that they don't want to learn something they do not intend to use. Particularly something that requires some effort to learn, which cannot be learned by reading a book or watching a video.

I think what *really* burned some folks' bacon was that, since most people don't come to ham radio with Morse Code knowledge, it put all new hams on the same level in one way. The Ph.D and the big bucks businessman found themselves at the same table as the grade-schooler when it came to learning code. Worse, the grade-schooler might very well out-do them! Some folks do not like that kind of equality.

I still remember the reactions of some (not many) older, more-experienced hams when they found out I was a teenage Extra. It *really* bothered them!

Voting with my wallet always makes me feel better. And just to make me
feel even better, I read QST for years at the bookstore for free....

>>The Technician was meant for those who were more interested in VHF/UHF
>>experimentation than HF operating.

>The license is for operating, not building.

I kind of set you up on that one. What you thought was my statement
was really your own statement. "The Technician was meant for those
who were more interested in VHF/UHF experimentation than HF
operating." is a direct quote from "The Past 50 Years of Amateur Radio
Licensing part 1" which *you* authored. So in those many paragraphs
you posted in reply, you were arguing with yourself... ;-)

>Being a skilled radio operator isn't being "an involuntary human modem".

Being a skilled radio operator in modern times does not require the
use of an ancient obsolete manual code.

>Who decides what is "obsolete"?

Obsolete is a subjective term. When an object finally becomes obsolete
most people can recognize it, and they upgrade to more modern
products. For example most people would agree that the 20+ tube 1950s

vintage TV set I watched as a kid is now quite obsolete. Likewise a
many tubed 1950s vintage shortwave receiver. Both would still work.
Both could still be used. But both are quite obsolete.

>I still remember the reactions of some (not many) older, more-
>experienced hams when they found out I was a teenage Extra. It
>*really* bothered them!

You misread them. They just didn't like a braggart...

Well you should have been kicked out of the bookstore. Most stores that I'm familiar with will let you thumb through material but will NOT let you stand there (or sit there) and read something.

CW /certainly/ isn't obsolete! I can make QSOs with just a few Watts that you could only /dream/ of achieving with /Kilowatts/ - and it can only be done with CW!

Bob

I find it calming and even kind of cool that I can walk around the house and follow a QSO in CW without having to carry a laptop and battery pack on my back to translate. I can even copy it easier than some people's voices with 5 times the power. But I can see how some might want everyone to think it's obsolete or even have us all executed for our insolence against the revolution!

What you have to realize, is that there are those "out there" who would consider HAM RADIO to be OBSOLETE because we don't pay for airtime.

The code test is no more! Viva La Revolucione! So now the war should be over!

So now life should go on. People should be allowed to use voice, or learn morse code, talk like computers, go have a sex change, jump off the Golden Gate bridge, run for president, or whatever they feel like as long as the taxpayer doesn't have to foot the bill.

The Barnes and Noble in my town actually provides chairs for you to sit and read magazines and books. Many of the chairs are overstuffed. I would say they have a different philosophy than your bookstores.

And I think B&N know what they are doing since I seldom leave there without buying at least $30 worth. More if the XYL is along.

My QST boycott is purely personal satisfaction, not financial.

My local ham store once complained that I was looking too long at the magazine rack. (It might have been a QST.) Over the years I had bought several $1000 in ham rigs. Being shortsighted has cost them thousands more in business since I still go there to look at the rigs, but now do my buying online .

Again I vote with my wallet, because it makes *me* feel better. I don't have any delusions that it really bothers the businesses.

I meant in this design...
http://www.realhamradio.com/hvreg.pdf

A safety ground connection is used for
120V loads because there's no neutral
taken from the AC line connection.

They should have used a four pole connector
and run a neutral as well as ground to the
power supply.

The ground and neutral are tied together
at your service entry.

You could connect two 120/240 transformers with
the primaries in parallel and the secondaries in
series. Then you'd have 480AC source which makes
a decent input to a doubler for about 1200VDC output.

There's nothing wrong with blood and thunder supplies
except the weight and the stored energy. If the parts
are available the cost factor might win out.

> I never saw where the neutral and ground tied together. The closest
> thing I could see was on the HV side of the transformer where one side
> is tied to ground. This is OK. I did find in another service manual
> where it warned about not having the mounting screws to the power

Even Barnes & Noble will object if you read an entire magazine or entire
book.  They are not a library but a business.  The chairs and atmosphere are
so you can SAMPLE the reading material not spend the day reading.

I agree, I understand the commercial version of this has been
redesigned hopefully addressing some of the issues you mentioned.

I had given some thought to using the transformers as you discribe but
for right now my purpose is to learn abut and build a switching power
supply.

Jimmie

>material not spend the day reading.

I *sampled* QST and *bought* another magazine or book. The bottom line
$$ for B&N was the same or more. Your tears are for the wrong entity.
B&N made money because I was drawn to their 'free sample' QST
magazine. QST is the one who lost money, but then that's what voting
with your wallet is all about...

Short answer, IGBTs are much better but not as good as MOSFETs.
In many cases they're good enough that the turn-off tail can be
ignored with very minor accommodation if any. In some cases an
IGBT may be superior than a MOSFET because you don't have to worry
about the switches RDSon drifting apart with temperature.

Though now days you can buy a 75V 120A 0.0004 Ohm MOSFET in a
T0-220 package... I guess RDSon isn't much of an issue.

The main problem with both IGBT and regular old bipolar transistors
in a push-pull circuit is the turn-off tail. The MOSFET does not
have a turn-off tail. There are two classes of IGBT, punch-though
and non-punch through. The punch-trough devices have better turn-off
times but are more fragile. Lately I've been using Trench Field Stop
IGBT's and they're very good.

There are several means of preventing imbalance of the transformer
in driven (not self oscillating) converters. The PWM will adjust
the on-time to compensate for the tail as it regulates the output
voltage. You can sense the differences with a circuit that converts
time to voltage (a capacitor and a current source) then make the
correction.

There are clever flux balancing windings that can be added. One
Unitrode app note describes how this can be done in the course of
presenting a half-bridge power converter. I can't recall the
document number.

In the half bridge and full bridge sometimes a capacitor in series
with the primary wdinding prevents saturation. I think you could
build a two capacitor divider across the input voltage and at the
center connect your transformer centertap lead. Then as the
imbalance increases the voltage at the center tap with shift
to compensate for it. I've seen half bridges built this way...
might work for a push pull... just guessing as I've never tried it.

A very small gap (0.001-0.003") will prevent saturation if the
imbalance is minor and not decrease the magnetizing inductance
too much. Sometimes any decrease is unwelcome though.
A distributed gap material like powdered-iron, koolmu, MPP
or sendust, might be useful if you expect to have flux imbalance
problems.

Pulse by pulse current limiting will mask the problem, so the
transformer is in saturation but not far into it and the current
limit keeps it from destroying the switches. Kinda risky to rely

on this alone but it's helpful combined with other measures.

In a current fed converter the transformer may saturate and then
switches are effectively connected directly to the current source.
No harm done! A current fed push-pull is a rugged topology. The
VAX8800 computer uses one for its control and start-up power supply.

Sounds like you're building a receiver with only one tube in it (a 7360)
and everything else solid state. Then again the 7360 probably makes a
very good product detector too.

No, it applied to 1000 MHz and below, back when the Technician was created.

Originally the treaty required Morse Code testing for all amateurs. Then in the late 1940s (1947 Atlantic City conference, IIRC), additional wording was added that removed the requirement for licenses that only allowed operation above 1000 MHz.

Over time that 1000 MHz limit was lowered, until it finally reached 30 MHz. And then in 2003 the whole code test thing was made optional.

> Techs couldn't go there.
> The treaty wouldn't apply to them.

The treaty in effect in 1951 applied to them.

> >A lot of VHF/UHF experimenting in those days did use

> justification
> is there for requiring the code test back then?

1) The treaty
2) Those modes were new back then.

The big question is, how many Techs actually did that stuff?

> >Was it [incentive licensing] really a screw up?
> >I think the real mistake was back in 1952.
>
> My old boss used to moan bitterly about the 52 license change
> when I worked
> for him in the 50s. He had been a Class A.

And he still was, only they called it Advanced and it made no
difference in privileges.

> But the difference is that in
> that change he *didn't lose* any privileges.

Instead, a lot of hams got them for free.

> He did lose privileges with the
> later Incentive Licensing change though. Which change do

Sounds like a sense of entitlement to me.
>
> >You can just imagine the reaction from hams who'd worked hard > > to get

> >flooded with Generals and Conditionals who had the same privileges.
>
> Probably like having the HF frequencies flooded by no-coders... 8-O

No, much worse.

The FCC has been reducing license requirements for almost 30 years, so
the final dropping of the code test should have been no surprise for
anyone. In fact I am still amazed that it took FCC 3-1/2 years to do
it after the treaty changed. I figured six months, tops.

But in the late 1940s the FCC went through a long process of
developing a new license structure that was a lot more complex than
the old ABC system. And when they rolled it out, one of the big

features was that the all-privileges license would be harder to get.

Then at the last minute they tossed away most of the idea and went in a completely different direction.

> >Another incentive would be increased power.
>
> If I were made boss, the maximum power allowed for any class
> would be 100W.
> And if used as an incentive, start at say 25 W for the entry
> license.

How's anybody gonna work EME with that?

> Just
> think of the reduction in neighbor complaints. Just think of the
> increase in operator skill...

But to do it you'd have to take privileges away from almost every ham. Worse, they could not get those privileges back.

You'd also make a lot of expensive gear practically worthless.

> >Who will be the very last Novice? The very last Advanced? How long
> >will it take for those license classes to disappear?
>
> They will likely disappear when they change to one license...
> (Like the Class A disappeared.)

But the Class A didn't disappear.

In the 1951 restructuring, it was renamed "Advanced", and survives to this day. When it was first closed to new issues at the end of 1952, FCC still kept it on the books. That made a big difference in 1968 and 1969 when the IL changes happened, because Advanceds had a lot more 'phone space than Generals after those changes.

The very first ARRL HB I ever owned (1967) used the 7360 in the mixer stage of a classic receiver (HB67) as well as another design (junior misers dream). The first receiver was an 80 meter single conversion set with a crystal controlled converter ahead of it. Similar commerical designs were the HA350 and the 2B. The HB67 used a 6D10 compactron as the first mixer/oscillator in the converter section. The MMD receiver had the 7360 in the front end (NO RF stage) with a first IF of 3300 KHZ. An RF Q multiplier was used instead of the RF stage. As you mentioned the oscillator injected into the deflection plates in both cases

This is probably what you mean but no new Advanced Class licenses are
issued any more. If you have one, you can renew indefinitely, but no
more new ones.

Scott
Used ta be an Advanced Class

No - the RF amplifier stage is a variable mu pentode, and there are more variable mu valves used in the IF, another 7360 for the product detector, and the rest is solid state. The hybrid approach seemed best - for example, the variable current drawn by the audio stages is /entirely/ isolated from the IF supply, the front end supply and the local oscillator supply. At the moment, it's a single conversion superhet, with a 10.7 MHz IF (because I have 10.7 MHz filters), though I'm considering making it dual conversion, with a very high first IF, to improve the inherent image problems.

C.

Thanks Rich!

On Sep 17, 4:55 pm, "Rich Klestinez" <replytogr...@noplace.cc> wrote:
>> I would not go through the trouble of unbalancing the transformer

I didn't mean to... The idea was to generate two symmetrical and opposed signals by putting an un-bal transformer between the VXO and a first push-pull stage made with just two sections, charged with rebuilding near-square waveforms.

I matched neither driver sections nor MOSFETs,but I did hear that both can be a bit variable. Apparently the chip drivers are normally used without equalization (to the surprise of quite a few authours). As for MOSFETs, I saw several amp designs with a single separate bias trimmer, or with a single special driver chip, for several devices. I have separate trimmers, I didn't bother to check if the 1-mA voltage was the same for both - but I will. That may have helped equalize the switching point in terms of RF voltage. As for the different on-state resistance, I guess it's more critical if one has devices in parallel - in a push-pull a particuarly low resistance device won't hog the current.

>> One other thing comes to mind is that with a torrid core at high current
>> and a high frequency, then symmetry of the winding itself is critical.

Yes, I've been extremely careful. Winding is trifilar, twisted, I took care to have symmetrical twist pitch and winding spacing.

>> torrid core

Torrid indeed. Now I have a tiny .82 core and thin wire too. At normal duty cycle all is fine, after 120s keydown one risks minor burns - but the MOSFETs barely get warm.

Coincidentally, I just got several 10s of feet of Raychem "high performance" wire after helping assemble a prototype 4-fuel car (3 liquid fuels + plugin recharger). 1.5sqmm, silver plated stranded copper alloy, thin 600V radiation-crosslinked high temperature insulator. I've been verbally told the 1/2sqmm variety can carry 30A (I asked as I worried it would not bear 3.5). I will try it on a larger core. I already recovered the ferrite of a 1-kW Hi Gain balun, but I want to see detailed wire specs first. Once stripped, this wire should do well in hi-Q coils too.

Awsome but really good wire!

If the Fet's are just barely warm it is my guess that you are driving them well into saturation and that good. As far as the core getting that hot, well that's not so good.
I digress. Some years back (70's) I tried to model the BH vs temperature of some high power cores that I was using at 452 Khz. They were getting very hot and we couldent figgure out why. Upon observing the BH curve at 452 Khz at 101% saturation there were bumps and little knots on the curve, they were really temperature dependant as well. Turned out (remember this was in the 1970's) this was a combination of grain size and a purely mechanical effect (pizoelectric). We switched to a different material with a very fine grain domains and the cores ran cool. I nearly wore out my Hemi 256 slide rule on that one. Still have the darn thing.   Nowdays core selection is much easier for high current high frequency uses. Pick a core empirically do your design and take advice from the wisdom of the below.

FYI. Adams magnetic products, Tom Corrigan Applications Engineer, 1-800-747-7543 or his direct line 630-359-9445. A really good guy and reps several lines of cores. Of course there is always the Ferroxcube area application engineers that are some of the best in the world that I have worked with in the past year. They will take the time to help you, however, you should be conversant in the terms of the language of magnetics or you wont understand what they mean.

Its a challange, but the rewards are great. You will have a transmitter that will be reliable and reproducible.

rich
in Texas

PS I have retired now (66 Yrs old). Not a ham yet. As soon as I get most of my honey-doos done I am considering trying for a licence.

I work with a couple of pieces of equipment that synthesises a
repetitive waveform by playing back the waeform from a ROM. I thought
I could do something like this to control the on-off timing of the
IGBT. This would set a minimum time between turn on and turn off and
the rest would be controlled by PWM.

As I see it you have a condition where both transistors are off at the
same time and both are on at the same time during parts of each cycle.
Adding another gate to equalize the propagation time would be the
first thing I would do.  I would want to have my o'scope working
before I started playing with turns on the transformer.

This is one advantage of the flyback and asymmetrical forward
converters. They will reset if there's enough dead time.
So in those cases your ROM circuit would do the trick.

Symmetrical topologies like push-pull, half-bridge and
full-bridge can saturate even if there is plenty of dead
time.   The core is always being driven by the control
circuit, so it has no time to relax, If the drive isn't
equal and opposite for each half cycle there is an offset
which the core accumulates. Eventually it will saturate.
unless there is some means to compensate for the imbalance
of the drive (like a coupling capacitor.)
So here the ROM circuit will not help.

Do you have the sources? I couldn't find anything but 30MHz. But I'll
stand corrected since you're certainly the undisputed historian here.

>What mode would a 1950s or 1960s ham use for moonbounce? Aurora?
>Meteor or tropo scatter? Satellite comms?

CW was the best weak signal mode in those days. Your point?

>You can just imagine the reaction from hams who'd worked hard > > to get
>their Advanceds or Extras, then suddenly found the HF 'phone
>bands flooded with Generals and Conditionals who had the same privileges.

>>Probably like having the HF frequencies flooded by no-coders... 8-O

>No, much worse.

Ouch. I guess you don't like no-coders on your HF bands.

>> If I were made boss, the maximum power allowed for any class
>> would be 100W.

>How's anybody gonna work EME with that?

EME is possible with a 100 watts. But CW ain't up to it. It takes
digital signal processing...

>But the Class A didn't disappear. In the 1951 restructuring,
>it was renamed "Advanced",

In a prior post you said the Tech+ will "disappear" because it will be
renewed (and thus renamed) a Tech. Now you say the Class A *didn't

disappear* when it was renamed as the Advanced. Can't have it both
ways...

 From your last post:
"The first license class to disappear completely will be the Tech
Plus, because FCC has been renewing them as Technician since April
2000. In another 19 months the last Tech Plus should disappear."

I think I get it. Would this explain why in a push-pull topology after
the transistors have been replaced a couple of times the power supply
just keeps failing for no apparent reason?

Are you saying that in other topologies it doesnt saturate or that it
doesnt matter if it does?

Ordered Abe's book.

Jimmie

As I see it you have a condition where both transistors are off at the same time and both are on at the same time during parts of each cycle. Adding another gate to equalize the propagation time would be the first thing I would do. I would want to have my o'scope working before I started playing with turns on the transformer.

Jimmie

If I understand you the IRF fets are in push pull. If this is the case then at no time should both transistors be conductiing at the same time ever. There should be a dead band between when one transistor conducts and the other is turning off.

Look up the results of the various World Radio Conferences down
through the years. A good starting place would be the 1947 Atlantic
City conference.

The QST archives are useful if you're a member of ARRL.

> I couldn't find anything but 30MHz.

You need to look further back than the 1980s.

> But I'll
> stand corrected since you're certainly the undisputed historian here.

Works for me!

> >What mode would a 1950s or 1960s ham use for moonbounce? Aurora?
> >Meteor or tropo scatter? Satellite comms?
>
> CW was the best weak signal mode in those days. Your point?

That if a license is supposed to be about experimenting, and Morse
Code/CW is the best mode to use for much of that experimenting, it
made sense to require a basic Morse Code test for that license.

> >You can just imagine the reaction from hams who'd worked hard

.

> >>Probably like having the HF frequencies flooded by no-coders... 8-O

> >No, much worse.

> Ouch. I guess you don't like no-coders on your HF bands.

Actually I don't think the 5 wpm Morse Code test was too much to ask.
But that's ancient history now.

What I was saying was that the Class A/Advanceds, and the Extras, of
1952 had been led to believe that the investment they had made in
earning those licenses would continue to be paid off by having more
privileges. All the FCC actions up to that time indicated it.

But at the last minute the FCC did the opposite.

> >> If I were made boss, the maximum power allowed for any class
> >> would be 100W.

> >How's anybody gonna work EME with that?
>
> EME is possible with a 100 watts. But CW ain't up to it. It takes
> digital signal processing...

Actually that's not true. Hams have done EME on microwave frequencies
with less than 100 watts and CW. But it takes a high gain antenna.

> >But the Class A didn't disappear. In the 1951 restructuring,
> >it was renamed "Advanced",

> In a prior post you said the Tech+ will "disappear" because it will be
> renewed (and thus renamed) a Tech.

That's right. It's been happening since April 2000.

> Now you say the Class A *didn't
> disappear* when it was renamed as the Advanced. Can't have it both
> ways...

There's a difference between a class disappearing and being renamed.

When the last Tech Plus either expires or is renewed as a Tech, the
Tech Plus class will have disappeared, having been merged with the
Tech. Just like what happened to the Conditional class back in the
late 1970s.

But the Class A/Advanced folks were and continue to be kept as a separate license class.

One project that I have been considering would be a re-creation of the classic Drake 2B receiver. This receiver was a dual conversion 80 meter receiver with an additional converter for other bands (making it a triple conversion). The receiver covered 600khz of the 80 meter band (3.5-4.1 mhz), the first IF was 455 khz, and the second IF was 50 khz. I have several sets of IF cans from BC453 receivers (85khz) and a 2.7 khz Collins filter that could be used instead of an IF transformer for the first IF.

I was thinking of using compactrons in the set, a single 6AR11 for the 85 khz IF, a 6D10 for the product detector and bfo, a 6AF11 for the AF stage and S meter amp. A 6AG11 would serve as an AGC tube and AM detector. The second (third?) mixer would be a 6BE6 (455->85), the first and second mixers would be 7360's (expensive!). The first (xtal) hfo would be solid state (maybe a pll), the second hfo (vfo) would also be solid state. I have several nice three gang capacitors from ARC-5 receivers with dial gear drive that would work nicely. The completed set would look more like the 2C because of the dial unless I ever find another Edystone dial. (I had one in the junk box for a few years and sold it on ebay to someone building an HBR. Got a kings ransom for it too).

The 6JH8 should work as well as the 7360 in a receiver mixer.
Swan changed to the 6JH8, probably for cost reasons.
(http://members.shaw.ca/pacifictv/cartridg.htm)

Not to make you feel bad, Ken... But, I still have an Eddystone
squirreled away for my HBR project. I think the Drake 2C
version makes more sense, though. The plug in coils and
oscillator LO scheme used by W6TC in the HBR
series leaves a bit to be desired.

Pete

```

Hard to say. Sometimes other parts are wounded and cause the transistor on-times to be slightly different. Often a base drive component, usually a resistor, changes value. Some lousy designs just won't work without selected transistors required to match the on-times. It only requires a small imbalance for the push-pull transformer to accumulate enough flux to eventually saturate. If the core is steel or powdered iron which can be magnetized by the fault current of the first failure sometimes (rarely) that causes problems too.

The other topologies we've discussed are more forgiving. BUT if the switch is on for too long, or the voltage applied to the winding too high, causing the flux density that the transformer can sustain to be exceeded, it will saturate. The current will then rise quite rapidly the sparks will fly.

It's just that they're not senstive to slight variations in the on-time of the switch. They reset the transformer completely during the dead time, so they don't accumulate any flux from on-time imbalances.

An exception is current fed symmetrical topologies which are just as senstive to imbalance. If the transformer saturates the fault current is controlled by the inductor feeding the converter and the current gradually increases. So the control circuit can catch the fault before the transistors are turned into lumps of glass.

Some topologies rely on saturation in order to function, like the royer (and some forms of blocking oscillator supplies) where saturation removes the positive feedback base drive and allows the switch to turn off. Nasty things but sometimes useful for low parts count, low-power, converters.

I'm sure you'll find Abe's book helpful. I still re-read it from time to time.

Well the plug in coil stock used by W6TC are also unobtainium these days
too. It IS possible to by raw polystyrene tubing of the right size, and
glue onto bases from dead tubes, or tube base plugs (both of which are
available from time to time). The APC variable caps are getting rare
these days, but good quality ceramic trimmers would sub and these are
not TOO hard to find.

I have a bunch of turret tv tuners with the removable strips and also
gave thought to building a receiver similar to the HBR's but with toroid
core coils switched in the tuner strips. I don't know if the toroid
cores were available to W6TC and if he would have used them.

I also have a dial drive from an HRO receiver if I ever get the desire
to build something even more antedeluvian!

With digital processing it can be done with a Yagi. You think we ought
to add a separate digital processing test to the Tech?

The APC caps (silver plated brass are needed for the LO coils) are still available. I've read that over one million a month were produced during WWII. How true that is, I don't know, but it was on a webpage dedicated to the history of Hammarlund. You have to shop around, but I've picked up a few dozen for around two bucks each.

The National polystrene coils were becoming scarce by the time the last HBR ran in QST. Bill (exray) uses Garolite XXX tubing (phenolic) for his plug in coils; a bit pricy for my tastes. Ted's coils had Qs of around 150 or so.

I'm going to try using fiberglass tubing--fortunately I have the poor ham's Q-meter (Heath QM-1) to verify the effectiveness of that material. A kind soul sent me a few dozen expired tubes to salvage the bases from. There's always plastic pill bottles, they've been tried and pass the Q-Meter test.

> I have a bunch of turret tv tuners with the removable strips and also gave thought to building a receiver similar to the HBR's but with toroid core coils switched in the tuner strips. I don't know if the toroid cores were available to W6TC and if he would have used them.
>

W6TC went through great pains to eliminate drift in the LO coils, I don't know if toroids are the best choice for oscillator coils.

I'm sure you're familiar with the turret tuner in the RCA TW-2000?

> I also have a dial drive from an HRO receiver if I ever get the desire to build something even more antedeluvian!

Now you're talking!!

Pete

I remember Allied radio and Lafayette radio both carrying those polystyrene coil forms as late as the early 70's (The last HBR article was in '64 IIRC). Those coil forms were NOT made by National Radio, the National coil forms were made of dark brown plastic (bakelite?) or ceramic material. Millen also made some plug in coils that were made of an orange colored bakelite like material. The '67 HB had a novice transmitter (1625 final) that used those coil forms, Allied Radio part numbers given.

I had a few of those coil forms at one time purchased to build a one tube regenerative receiver from the 'boy electrician' book by Alfred Morgan. Barry electronics had the 1H4G tubes for 50 cents back then.

Ocean State Electronics was carrying the polystyrene coil forms a few years ago. They also had some 'cloned' forms that would fit the old National Radio SW3 receiver (same weird 6 pin base).

You can use the same grinding powder that ATM's (amateur Telescope makers) use to grind mirrors for grinding crystals. You want the fine stuff #400 or finer. www.gotgrit.com has this stuff cheap.
Grind the crystal against a piece of scrap plate glass. I've had mixed results, I've moved a few rocks a few hundred khz and I've also killed some trying to move them just a few hundred hz.

Only grind ONE side of the rock, put a pencil mark on the other so you don't mix this up. Wash the crystal well after each grinding session and only handle it by the edges, you don't want your finger sweat or oils getting on the crystal. Grinding motion should be a figure 8, use light pressure and don't push down on the middle of the crystal, handle by the edges while grinding.

If you do kill the crystal, you might be able to get it to start again by light grinding using a different motion. Also try holding the crystal vertical and grind the edges slightly. Measure the thickness (carefully!) with a micrometer all around. If you ground a 'wedge' shape into the rock this will also kill and and the cure is to regrind putting more pressure on the fatter end.

I have quite a few useless FT243 rocks in the junk box, one of these days I'll probably try moving a few of them to a more useful frequency.

BTW some of those 'useless' frequency rocks do multiply out into some ham bands.

A few examples from my junk box:
4845khz -> 29070khz (10 meters)
6050khz -> 18150khz (17 meters)
6025khz -> 18075khz (17 meters)
4785khz -> 28710hkz (10 meters)
5300khz -> 21200hkz (15 meters)

Brass slug acts as a shorted turn, absorbing rf and decreasing
effective inductance. You can tune a circuit with a link coupling coil
of a few turns connected to a low ohm value pot!

I searched on Mouser Electronics website. Says the part is obsolete,
but they have a link under the "Quote" section, so maybe they have some
available???

http://www.mouser.com/Search/Refine.aspx?
Ntt=*S310CCTK*&N=1323038&Ntx=mode%2bmatchall&Ns=P_SField&OriginalKeyword=S-310-CCT-K&Ntk=Mouser_Wildcards

Digikey lists the part, but shows a quantity of zero...

http://search.digikey.com/scripts/DkSearch/dksus.dll?Detail?name=CJ210S-ND

One last ditch effort...

http://www.google.com/search?hl=en&q=S-310-CCT-K&btnG=Google+Search&aq=f&oq=

Good luck with the search...this may be a tough one :(

Scott

```

No, I do have a source.

Here are the facts:

Amateur radio was first officially recognized as a separate radio service at the Paris radio conference of 1927. As part of the regulations/treaty, all amateurs had to be Morse Code tested.

At the Atlantic City radio conference of 1947, the Morse Code test requirement was modified so that a Morse Code test was not required for amateur licenses that only allowed operation above 1000 MHz. This rule was in effect when the Technician Class license was created by FCC in 1951. There's an article explaining all this in QST for October, 1947.

At the Geneva radio conference of 1959, the requirement was modified so that a Morse Code test was not required for amateur licenses that only allowed operation above 144 MHz. This is explained in a QST article in the issue for March, 1960.

At the radio conference of 1979, commonly called "WARC-79", which resulted in the 30, 17 and 12 meter bands, the requirement was modified so that a Morse Code test was not required for amateur licenses that only allowed operation above 30 MHz. This is explained in a QST article in the issue for February, 1980.

So the USA could not have created the Technician license in 1951 without a code test unless that license had not allowed any operation below 1000 MHz.

When were these "dark days"?

It's not about "luck", it's about knowing the history.
